The unit hydrograph method was used to determine the peak flow rates and volumes in order to adequately size the proposed basin and chamber detention systems to address increased runoff mitigation. Unit hydrographs were performed for both the 24-hour existing condition and developed condition only in the preliminary condition since it was assumed that the 24-hour condition will require the greatest mitigation volume. The existing condition is used to establish a baseline for comparative purposes. The developed condition is used for design purposes, it was utilized in the basin routing analysis in order to size and analyze the proposed basin and chamber detention systems. The unit hydrograph analysis for both the existing and developed condition was conducted for a total of 156.8 acres. This comprises the entirety of the proposed development with the BSS project site.

In the existing condition analysis, the overall project site was broken up into two areas. Approximately 106.4 acres are labelled as Area A and is tributary to the existing streambed area to the west of the project site. The remaining 50.4 acres are labelled as Area B and are tributary to a region of the streambed to the south of the project site. In the proposed condition, Area A is divided into a West Area and North Area (corresponding to Building 1 and Building 3, respectively). The West Area consists of approximately 55.3 acres while the North area is approximately 33.8 acres. Area B is referred to as the South Area in the developed condition and corresponds to the Building 2 project site, consisting of approximately 67.8 acres. In the developed condition, approximately 17.4 acres of area which was tributary to Area A in the existing condition have been included in the development of the South Area (part of the existing condition Area B). Therefore, the developed South Area will be over mitigating for flows as a greater area, and therefore greater discharge, is included in the developed condition analysis. While the existing condition Area A will be under mitigated once developed, the overall BSS site will be mass graded together as grading will require cut from the Building 2 area, in Area B, to be used in fill for mass grading of the Building 1 project site. Therefore, overall the BSS project will be fully mitigated once developed.

The following table summarizes the results of the unit hydrograph analysis:

Table 4 – Unit Hydrograph Results

EXISTING CONDITION - AREA A (WEST & NORTH)					EXISTING CONDITION - AREA B (SOUTH)

The unit hydrograph output files and hydrology map have been included in Appendix C.

BASIN ROUTING ANALYSIS

A routing analysis was completed to demonstrate that the basin and CMP chamber systems contain substantial volume needed to mitigate flows down to existing condition peak flow rates.

Basin routing calculations were conducted for each building area (west, north and south). A stage-storage-discharge table was determined for each area. The stage-storage-discharge tables provide input data at select elevations in the basin and/or chambers which will determine the storage and discharge at each point based on the mitigation configuration of the outlet structures.

In the proposed condition unit hydrograph analysis, the North Area outlets to the south of the Building 1 project site. Runoff from this region will connect with the outlet of the existing condition Area A, as the streambed into which Area A outlets runs from the southern portion of the Building 1 project area to the northwest along the western boundary. In the existing condition, the entire Area A generally drains to the southwest. Approximately 16.6% of Area A drains more towards the southern boundary before being conveyed to the west along the streambed. This area corresponds to the developed North Area (Building 3). The remaining portion, approximately 83.4%, correlates to the developed West Area (Building 1) and drains directly to the western boundary of Area A. For the developed condition West Area and North Area, a ratio of the areas was used to determine the existing peak flow rates which serve as the limits for the routing analysis of each area. An exhibit showing the portion of the existing condition Area A which flows south can be found in Appendix C.

For the BSS – Building 1 area, the proposed outlet structure consists of four 4-inch orifices with an invert set at the water quality ponding elevation of 2.4 ft above the chamber bottom. This orifice mitigates the 2-year storm event. A 1.5-ft weir is proposed at the maximum ponding depth for the 2-year, 24-hour storm (a depth of approximately 5.82 ft). This orifice mitigates for the 5-year storm event and creates a maximum ponding depth of 6.96 ft above the chamber bottom. At the 5-year ponding depth, a 7-ft weir is proposed to mitigate the 10-year and 100-year storm event. The 100-year storm produces a maximum ponding of 7.99 ft, which is below the 8 ft depth of the top of the chambers. The routing analysis produced a maximum drawdown time of 88.6 hours within the chambers. While this exceeds the 72-hour limit for above ground basins to prevent vector issues, the CMP detention system consists of underground chambers and therefore vector issues are not anticipated even with a high drawdown time.

For the BSS – Building 2 area, a constant flow rate of 9.4 cfs was assumed for the basin in order to account for the expected infiltration within the basin extents. This value was determined based on a recommended infiltration rate of 11.5 in/hr within the basin (see Appendix D for the infiltration report), the bottom basin area, and a factor of safety of 3. The water quality volume produces a maximum ponding of 1.4 ft above the basin bottom. Routing of the 2-year, 24-hour storm event shows that the infiltration within the basin is sufficient to meet the existing condition flow rates while producing 2.15 ft of ponding above the basin bottom. The proposed outlet structure consists of a rectangular weir with a length of 6 ft set at the 2-year storm ponding depth. This weir mitigates the 5-year storm event and produces a ponding depth of 2.67 ft. A 6-ft weir mitigates for the 10-year storm event and creates a maximum ponding depth of 2.98 ft within the basin. At the 10-year ponding elevation, a 6-ft weir mitigates for the 100-year storm. The 100-year storm creates a total ponding of 3.36 ft from the basin bottom, allowing at least 1 ft of freeboard below the top of the basin.

For the BSS- Building 3 area, the proposed outlet structure consists of a 3.5-inch orifice plate with an invert set at the bottom of the chambers. The water quality flows will be pumped out to be treated by the proposed bioretention basin therefore the chambers do not hold the water quality volume. This orifice mitigates the 2-year storm event. A 5-inch orifice is proposed at the maximum ponding depth for the 2-year, 24-hour storm (a depth of approximately 3.49 ft). This orifice mitigates for the 5-year storm event and creates a maximum ponding depth of 4.46 ft within the chambers. At this depth, a 0.8 ft weir is proposed to mitigate for the 10-year and 100-year storm events. The 10-year, 24-hour storm event creates

a maximum ponding of 5.16 ft while the 100-year storm creates a maximum ponding of 7.03 ft, which is below 9 ft depth of the top of the gravel which provides storage above the chambers as well. The routing analysis for the BSS – Building 3 detention chambers resulted in a maximum drawdown time of approximately 228 hours. While this exceeds the 72-hour limit for above ground basins to prevent vector issues the CMP detention system consists of underground chambers and therefore vector issues are not anticipated even with a high drawdown time. This is due to this area over mitigating as the developed Building 3 project area is larger than the portion of the existing condition Area A which is used as the limit for the routing analysis of this region. While the mitigation for both Building 3 and Parcel 4 are included in the BSS – Building 3 Area, Parcel 4 will be required to treat for water quality separately from Building 3.

The following tables present the result of routing analysis for the 2-, 5-, 10- and 100-year 24-hour storm events to demonstrate that the basin and CMP chamber systems provide the necessary storage volume needed to restrict the outflow to existing condition flow rates.

Table 5 – Basin Routing Results

		Existing Condition

Note:

**The Combined Peak Flow describes the flows exiting the site along the western and southwestern boundary of the site. This value is the sum of the peak flow rates generated by the West and North Areas in the proposed condition which have been routed to be less than the existing condition peak flow for Area A or within 10% of this value.*

***For the routing analysis of the South Area (Building 2), a constant flow rate of 9.4 cfs is assumed to be infiltrating within the basin extents (based on 11.5 in/hr infiltration rate, the basin bottom area, and a factor of safety of 3) and has been subtracted from the peak flow results from the routing analysis.*

The basin routing calculations and other hydraulic calculations have been provided in Appendix C. Based on the table above, the proposed infiltration basin and detention chambers for each building area have the capacity to mitigate for all the required HCOC storm events. All discharge flow rates in the developed condition are lower than or within ten percent of the flow rate exiting the site in the existing condition.

INFILTRATION REPORT

August 13, 2021

Exeter Property Group
4602 East University Drive, Suite 185
Phoenix, Arizona 85034

Attention: Mr. Andrew Greybar
Senior Project Manager

Project No.: **21G133-2**

Subject: **Results of Infiltration Testing**
Proposed E-Commerce Development
Cherry Valley Avenue, West of Fabian Lane
Beaumont, California

Reference: Geotechnical Investigation, Proposed E-Commerce Development, Beaumont, California, prepared by Southern California Geotechnical, Inc. (SCG), prepared for Exeter Property Group, SCG Project No. 21G133-1.

Mr. Greybar:

In accordance with your request, we have conducted infiltration testing at the subject site. We are pleased to present this report summarizing the results of the infiltration testing and our design recommendations.

Scope of Services

The scope of services performed for this project was in general accordance with our Change Order No. 21G133-CO, dated July 14, 2021. The scope of services included site reconnaissance, subsurface exploration, field testing, and engineering analysis to determine the infiltration rates of the onsite soils. The infiltration testing was performed in general accordance with the guidelines published in Riverside County – Low Impact Development BMP Design Handbook – Section 2.3 of Appendix A, prepared for the Riverside County Department of Environmental Health (RCDEH), dated December, 2013.

Site and Project Description

The subject site is located on the south side of Cherry Valley Boulevard, 1,500± feet west of the intersection of Cherry Valley Boulevard and Fabian Lane in Beaumont, California. The site is bounded to the north by Cherry Valley Boulevard, to the east by single-family residences (SFRs) and vacant lots, to the south by Brookside Avenue, to the southwest by the Redlands Freeway (Interstate 10) and to the west by vacant land. The general location of the site is illustrated on the Site Location Map, enclosed as Plate 1 in Appendix A of this report.

The overall site consists of several irregular to rectangular-shaped parcels which total 178.4± acres in size. The site is presently developed with three (3) single-family residences and several small abandoned buildings located in the northeastern area of the site. Remnants of shade structures including Portland cement concrete panels and sawed-off poles are present

throughout the northeastern areas of the site. Several above-ground storage tanks are also present throughout the northeastern area of the site. One of the smaller abandoned structures possesses a below-grade room with what appears to be a turbine. The remaining areas of the site are presently vacant and undeveloped. Five (5) circular to oval-shaped leech ponds are located in the west-central area of the site. Two (2) additional leech ponds are located in the south-central area of the site. Ground surface cover consist of exposed soil and moderate to dense native grass and weed growth. Several large trees are located in the southern areas of the site. Limited areas of trash and debris are located throughout the site.

Detailed topographic information was obtained from the conceptual grading plan prepared by Albert A. Webb Associates (Webb). Based on the provided plan, the northeastern to northern two-thirds of the site slopes downward to the southwest at a gradient of 4± percent. The seven (7) circular leech ponds located in the west-central and south-central areas of the site are surrounded by a berm that is 5± feet higher than the surrounding topography. The northwestern area of the site possesses several east-west and southeast-northwest trending drainage courses. The drainage features possess gradual to steep side walls with elevation differences of up to 15± feet below the surrounding topography. To the south of the leech pits, the site slopes towards the south to southwest at a gradient of 10± percent. The topography descends by 50± feet in this area. Another significant east-west trending drainage is located at the base of the descending slope, located in the southern-most region of the site. The drainage possesses gradual to steep side walls with an elevation difference up 10± feet below the surrounding topography. A hill, located to the southeast of this drainage, is approximately 20 to 30 feet higher than the surrounding topography. The hill possesses slope gradients ranging from 14 to 40± percent. To the south of the hill, the site topography slopes gently to the west at a gradient of 3.5± percent, where it meets up with a tributary drainage to the previously mentioned bisecting drainage. The area to the southwest of the bisecting drainage slopes to the west a gradient of 2.5± percent. Another hill with a north-facing descending slope is located at the southwest corner of the site. The slope has a gradient of 20± percent. The maximum site elevation is 2581± feet mean sea level (msl), in the northeast corner of the site. The minimum site elevation is 2406± feet msl, located in drainage swale channel located in the southern-most region of the site.

Proposed Development

Based on the conceptual site plan prepared by Webb, the site will be developed with three (3) new E-Commerce buildings. Building 1 will be 985,860± ft^2 in size, located in the western area of the site. Building 2 will be 1,254,000± ft^2 in size, located in the east-central region of the site. Lastly, Building 3 will be 358,370± ft^2 in size, located in the north-central area of the site. A cross-dock configuration will be constructed on Building 1 and Building 2, along the east/west and north/south building walls, respectively. Dock-high doors will be constructed along a portion of the southern building wall of Building 3. The buildings will be surrounded by asphaltic concrete pavements in the automobile parking and drive areas, Portland cement concrete (PCC) pavements in the truck court, and areas of concrete flatwork and landscape planters. Several new fill and cut slopes will be constructed along all permitters, as well as within the site. The new fill slopes will range from 10 to 40± feet in height and will possess slope inclinations not to exceed 2h:1v (horizontal to vertical). New retaining walls will also be required to establish the

new site grades. The new retaining walls will possess maximum retained heights ranging from 10 to 50± feet.

The proposed development will include on-site stormwater infiltration. Based on our conversations with the project civil engineer and the proposed site plan, infiltration systems will consist of two (2) below-grade chambers and one (1) detention basin. One of the infiltration chamber systems will be located in the northern area of the site (south of Building 3). The bottom of the chambers are expected to range from 28 to 34± feet below the existing site grades. The second infiltration chamber system will be located in the southern area of the site (south of Building 2). The bottom of the chambers are expected to range from 24 to 36± feet below the existing site grades. The detention basin will be located in the south-central area of the site. The bottom of the basin will be at an elevation of, approximately 10 to 43± feet, below the existing site grades.

Concurrent Study

SCG concurrently conducted a geotechnical investigation at the subject site, also referenced above. The investigation conducted for this project consisted of forty-four (44) borings advanced to depths of 10 to 50± feet, and seven (7) trenches excavated to depths of 6½ to 10½± feet below the existing site grades. Artificial fill soils were encountered at the ground surface of several boring and trench locations. The fill soils generally consist of loose to medium dense silty fine sands and clayey fine to medium sands. The fill soils possess a disturbed and mottled appearance, resulting in their classification as artificial fill. Native alluvium was encountered beneath the artificial fill soils or at the ground surface at several of the borings and trench locations. The alluvial soils extend to depths of 2½ to 10± feet below ground surface in the northern areas of the site, and 25 to 50± feet below ground surface in the southern areas of the site. The alluvial soils generally consist of loose to very dense silty fine sands and silty fine to medium sands. Older alluvial soils were encountered at the ground surface, beneath the artificial fill, and/or beneath the alluvium of the boring and trench locations, extending to at least the maximum depth explored of 50± feet below ground surface. The older alluvial soils generally consist of medium dense to very dense silty fine sands, silty fine to medium sands, silty fine to coarse sands and silty fine sands to fine sandy silts.

Groundwater

Groundwater was not encountered at any of the boring or trench locations. Based on the lack of any water within the borings and trenches, and the moisture contents of the recovered soil samples, the static groundwater table is considered to have existed at a depth in excess of 50± feet below existing site grades at the time of the subsurface investigation.

As part of our research, we reviewed available groundwater data in order to determine the historic high groundwater level and recent groundwater level for the site. The primary reference used to determine the groundwater depths in this area is the California Department of Water Resources website, http://www.water.ca.gov/waterdatalibrary/. The nearest monitoring wells in this database are located in the northeast corner of the site. Water level readings within one of these monitoring wells indicates a historic high groundwater level of 317± feet below the ground surface in September 1990. Water level readings within another of these monitoring

wells indicates a recent high groundwater level of 412± feet below the ground surface in December 2020.

Subsurface Exploration

Scope of Exploration

The subsurface exploration conducted for the infiltration testing consisted of sixteen (16) infiltration test borings, advanced to depths ranging from 10 to 43± feet below the existing site grades. The infiltration borings were advanced using a truck-mounted drilling rig, equipped with 8-inch-diameter hollow stem augers and were logged during drilling by a member of our staff. The approximate locations of the infiltration test borings (identified as I-1 through I-16) are indicated on the Infiltration Test Location Plan, enclosed as Plate 2 of this report.

Upon the completion of the infiltration borings, the bottom of each test boring was covered with 2± inches of clean ¾-inch gravel. A sufficient length of 3-inch-diameter perforated PVC casing was then placed into each test hole so that the PVC casing extended from the bottom of the test hole to the ground surface. Clean ¾-inch gravel was then installed in the annulus surrounding the PVC casing.

Geotechnical Conditions

Alluvial soils were encountered at the ground surface some of the infiltration borings, extending to depths of 4 to 32± feet below existing site grades. The alluvial soils in generally consist of loose to dense silty fine sands, silty fine to medium sands, clayey sands, fine to coarse sands, and fine to coarse sandy silts with variable gravel content. Older alluvium was encountered at the ground surface or beneath the alluvium at most of the boring locations. The older alluvium generally consists of medium dense to dense fine sands, fine to coarse sands, silty fine sands, silty fine to medium sands, and clayey fine to medium sands, extending to the maximum depth explored of 43± feet.

Infiltration Testing

As previously mentioned, the infiltration testing was performed in general accordance with the Riverside County guidelines: Riverside County – Low Impact Development BMP Design Handbook – Section 2.3 of Appendix A.

Pre-soaking

In accordance with the county infiltration standards all sixteen (16) of the infiltration test borings were pre-soaked prior to the infiltration testing. The pre-soaking process consisted of filling the test borings by inverting a full 5-gallon bottle of clear water supported over each hole so that the water level reaches a level of at least 5 times the hole's radius above the gravel at the bottom of each hole. The pre-soaking was completed after all of the water had percolated through each test hole or after 15 hours since initiating the pre-soak. Based on the results of the pre-soaking process, different infiltration procedures were used during the infiltration testing at the infiltration boring locations.

Infiltration Testing

Following the pre-soaking process of the infiltration test borings, SCG performed the infiltration testing. Each test hole was filled with water to a depth of at least 5 times the hole's radius above the gravel at the bottom of each test hole, and less than or equal to the water level used during the pre-soaking process. In accordance with the Riverside County guidelines, since "sandy soils" and "non-sandy" conditions were encountered at the bottom of the infiltration borings tests were run for an additional hour with measurements taken at 10-minute intervals for "sandy" conditions and 30-minute intervals for six hours in "non-sandy" conditions. After each reading, the borings were refilled to the correct water level above the gravel at the bottom of each test hole. The water level readings are presented on the spreadsheets enclosed with this report. The infiltration rates for each of the timed intervals are also tabulated on the spreadsheets.

The infiltration rates from the test are tabulated in inches per hour. In accordance with the typically accepted practice, it is recommended that the most conservative reading from the latter part of the infiltration tests be used as the design infiltration rate. The rates are summarized below:

Infiltration Test No.	Depth (feet)	Test Elevation (feet) MSL	Soil Description	Infiltration Rate (inches/hour)
I-1	22	2496	Red Brown fine to coarse Sandy Silt	4.0
I-2	25	2495	Red Brown Silty fine to medium Sand, trace coarse Sand	0.0
I-3	31	2494	Red Brown Clayey fine to coarse Sand, trace Silt	0.0
I-4	34	2496	Red Brown Silty fine to medium Sand, trace coarse Sand	0.0
I-5	24	2474½	Red Brown Silty fine to medium Sand, trace coarse Sand	4.4
I-6	25	2474	Red Brown Silty fine to medium Sand, trace coarse Sand	3.6
I-7	30	2474	Red Brown Silty fine to medium Sand, trace coarse Sand, trace fine Gravel	3.7
I-8	30	2474	Brown Gravelly fine to coarse Sand, little Silt	8.0
I-9	36	2475	Red Brown Silty fine to medium Sand, trace coarse Sand, some fine Gravel	4.2
I-10	35	2475	Brown fine to coarse Sand, trace fine Gravel, trace Silt	8.7
I-11	10	2446	Brown Silty fine to medium Sand, trace fine Gravel	0.8

I-12	14	2443	Red Brown Silty fine to medium Sand, trace coarse Sand, trace fine to coarse Gravel	4.8
I-13	28	2445	Brown fine to coarse Sand, little fine Gravel, little Silt	19.4
I-14	16	2444	Gray Brown Gravelly fine to coarse Sand, little Silt	13.5
I-15	27	2449	Red Brown Silty fine to coarse Sand, trace fine Gravel	15.7
I-16	43	2445	Red Brown Silty fine to medium Sand, trace coarse Sand	14.6

Laboratory Testing

Moisture Content

The moisture contents for the recovered soil samples within the borings were determined in accordance with ASTM D-2216 and are expressed as a percentage of the dry weight. These test results are presented on the Boring Logs.

Grain Size Analysis

The grain size distribution of selected soils collected from the bottom of each infiltration test boring have been determined using a range of wire mesh screens. These tests were performed in general accordance with ASTM D-422 and/or ASTM D-1140. The weight of the portion of the sample retained on each screen is recorded and the percentage finer or coarser of the total weight is calculated. The results of these tests are presented on Plates C-1 through C-17 of this report.

Design Recommendations

Sixteen (16) infiltration tests were performed at the subject site. As noted above, the infiltration rates at these locations range from 0 to 19.4 inches per hour.

Based on the results of the infiltration testing, we recommend the following infiltration rates for the proposed infiltration systems:

Infiltration System	Site Location	Infiltration Rate (Inches per Hour)
A	North-Central	0
B	South-Central	5.4
C	South-Central	11.5

We recommend that a representative from the geotechnical engineer be on-site during the construction of the proposed infiltration system to identify the soil classification at the base of the chamber system. It should be confirmed that the soils at the base of the proposed

infiltration system corresponds with those presented in this report to ensure that the performance of the system will be consistent with the rates reported herein.

The design of the proposed storm water infiltration system should be performed by the project civil engineer, in accordance with the City of Beaumont and/or County of Riverside guidelines. However, it is recommended that the system be constructed so as to facilitate removal of silt and clay, or other deleterious materials from any water that may enter the system. The presence of such materials would decrease the effective infiltration rates. **It is recommended that the project civil engineer apply an appropriate factor of safety. The infiltration rate recommended above is based on the assumption that only clean water will be introduced to the subsurface profile. Any fines, debris, or organic materials could significantly impact the infiltration rates.** It should be noted that the recommended infiltration rates are based on infiltration testing at sixteen (16) discrete locations and the overall infiltration rate of the storm water infiltration system could vary considerably.

Infiltration Rate Considerations

The infiltration rates presented herein was determined in accordance with the City of Beaumont and/or County of Riverside guidelines and are considered valid only for the time and place of the actual test. Varying subsurface conditions will exist in other areas of the site, which could alter the recommended infiltration rates presented above. The infiltration rates will decline over time between maintenance cycles as silt or clay particles accumulate on the BMP surface. The infiltration rate is highly dependent upon a number of factors, including density, silt and clay content, grainsize distribution throughout the range of particle sizes, and particle shape. Small changes in these factors can cause large changes in the infiltration rates.

Infiltration rates are based on unsaturated flow. As water is introduced into soils by infiltration, the soils become saturated and the wetting front advances from the unsaturated zone to the saturated zone. Once the soils become saturated, infiltration rates become zero, and water can only move through soils by hydraulic conductivity at a rate determined by pressure head and soil permeability. Changes in soil moisture content will affect the infiltration rate. Infiltration rates should be expected to decrease until the soils become saturated. Soil permeability values will then govern groundwater movement. Permeability values may be on the order of 10 to 20 times less than infiltration rates. The system designer should incorporate adequate factors of safety and allow for overflow design into appropriate traditional storm drain systems, which would transport storm water off-site.

Construction Considerations

The infiltration rates presented in this report are specific to the tested locations and tested depths. Infiltration rates can be significantly reduced if the soils are exposed to excessive disturbance or compaction during construction. Compaction of the soils at the bottom of the infiltration system can significantly reduce the infiltration ability of the basins. Therefore, the subgrade soils within proposed infiltration system areas should not be over-excavated, undercut or compacted in any significant manner. **It is recommended that a note to this effect be added to the project plans and/or specifications.**

We recommend that a representative from the geotechnical engineer be on-site during the construction of the proposed infiltration systems to identify the soil classification at the base of each system. It should be confirmed that the soils at the base of the proposed infiltration systems

correspond with those presented in this report to ensure that the performance of the systems will be consistent with the rates reported herein.

We recommend that scrapers and other rubber-tired heavy equipment not be operated on the basin bottom, or at levels lower than 2 feet above the bottom of the system, particularly within basins. As such, the bottom 24 inches of the infiltration systems should be excavated with non-rubber-tired equipment, such as excavators.

Basin Maintenance

The proposed project may include infiltration basins. Water flowing into these basins will carry some level of sediment. Wind-blown sediments and erosion of the basin side walls will also contribute to sediment deposition at the bottom of the basin. This layer has the potential to significantly reduce the infiltration rate of the basin subgrade soils. Therefore, a formal basin maintenance program should be established to ensure that these silt and clay deposits are removed from the basin on a regular basis. Appropriate vegetation on the basin sidewalls and bottom may reduce erosion and sediment deposition.

Basin maintenance should also include measures to prevent animal burrows, and to repair any burrows or damage caused by such. Animal burrows in the basin sidewalls can significantly increase the risk of erosion and piping failures.

Location of Infiltration Systems

The use of on-site storm water infiltration systems carries a risk of creating adverse geotechnical conditions. Increasing the moisture content of the soil can cause the soil to lose internal shear strength and increase its compressibility, resulting in a change in the designed engineering properties. Overlying structures and pavements in the infiltration area could potentially be damaged due to saturation of the subgrade soils. **The proposed infiltration systems for this site should be located at least 25 feet away from any structures, including retaining walls.** Even with this provision of locating the infiltration system at least 25 feet from the building(s), it is possible that infiltrating water into the subsurface soils could have an adverse effect on the proposed or existing structures. It should also be noted that utility trenches which happen to collect storm water can also serve as conduits to transmit storm water toward the structure, depending on the slope of the utility trench. Therefore, consideration should also be given to the proposed locations of underground utilities which may pass near the proposed infiltration system.

The infiltration system designer should also give special consideration to the effect that the proposed infiltration systems may have on nearby subterranean structures, open excavations, or descending slopes. In particular, infiltration systems should not be located near the crest of descending slopes, particularly where the slopes are comprised of granular soils. Such systems will require specialized design and analysis to evaluate the potential for slope instability, piping failures and other phenomena that typically apply to earthen dam design. This type of analysis is beyond the scope of this infiltration test report, but these factors should be considered by the infiltration system designer when locating the infiltration systems.

General Comments

This report has been prepared as an instrument of service for use by the client in order to aid in the evaluation of this property and to assist the architects and engineers in the design and

preparation of the project plans and specifications. This report may be provided to the contractor(s) and other design consultants to disclose information relative to the project. However, this report is not intended to be utilized as a specification in and of itself, without appropriate interpretation by the project architect, structural engineer, and/or civil engineer. The design of the infiltration system is the responsibility of the civil engineer. The role of the geotechnical engineer is limited to determination of infiltration rate only. By using the design infiltration rates contained herein, the civil engineer agrees to indemnify, defend, and hold harmless the geotechnical engineer for all aspects of the design and performance of the infiltration system. The reproduction and distribution of this report must be authorized by the client and Southern California Geotechnical, Inc. Furthermore, any reliance on this report by an unauthorized third party is at such party's sole risk, and we accept no responsibility for damage or loss which may occur. The analysis of this site was based on a subsurface profile interpolated from limited discrete soil samples. While the materials encountered in the project area are considered to be representative of the total area, some variations should be expected between trench locations and testing depths. If the conditions encountered during construction vary significantly from those detailed herein, we should be contacted immediately to determine if the conditions alter the recommendations contained herein.

This report has been based on assumed or provided characteristics of the proposed development. It is recommended that the owner, client, architect, structural engineer, and civil engineer carefully review these assumptions to ensure that they are consistent with the characteristics of the proposed development. If discrepancies exist, they should be brought to our attention to verify that they do not affect the conclusions and recommendations contained herein. We also recommend that the project plans and specifications be submitted to our office for review to verify that our recommendations have been correctly interpreted. The analysis, conclusions, and recommendations contained within this report have been promulgated in accordance with generally accepted professional geotechnical engineering practice. No other warranty is implied or expressed.

Closure

We sincerely appreciate the opportunity to be of service on this project. We look forward to providing additional consulting services during the course of the project. If we may be of further assistance in any manner, please contact our office.

Respectfully Submitted,

BORING LOG LEGEND

SAMPLE TYPE	GRAPHICAL SYMBOL	SAMPLE DESCRIPTION
AUGER		SAMPLE COLLECTED FROM AUGER CUTTINGS, NO FIELD MEASUREMENT OF SOIL STRENGTH. (DISTURBED)
CORE		ROCK CORE SAMPLE: TYPICALLY TAKEN WITH A DIAMOND-TIPPED CORE BARREL. TYPICALLY USED ONLY IN HIGHLY CONSOLIDATED BEDROCK.
GRAB		SOIL SAMPLE TAKEN WITH NO SPECIALIZED EQUIPMENT, SUCH AS FROM A STOCKPILE OR THE GROUND SURFACE. (DISTURBED)
CS		CALIFORNIA SAMPLER: 2-1/2 INCH I.D. SPLIT BARREL SAMPLER, LINED WITH 1-INCH HIGH BRASS RINGS. DRIVEN WITH SPT HAMMER. (RELATIVELY UNDISTURBED)
NSR		NO RECOVERY: THE SAMPLING ATTEMPT DID NOT RESULT IN RECOVERY OF ANY SIGNIFICANT SOIL OR ROCK MATERIAL.
SPT		STANDARD PENETRATION TEST: SAMPLER IS A 1.4 INCH INSIDE DIAMETER SPLIT BARREL, DRIVEN 18 INCHES WITH THE SPT HAMMER. (DISTURBED)
SH		SHELBY TUBE: TAKEN WITH A THIN WALL SAMPLE TUBE, PUSHED INTO THE SOIL AND THEN EXTRACTED. (UNDISTURBED)
VANE		VANE SHEAR TEST: SOIL STRENGTH OBTAINED USING A 4 BLADED SHEAR DEVICE. TYPICALLY USED IN SOFT CLAYS-NO SAMPLE RECOVERED.

COLUMN DESCRIPTIONS

DEPTH: Distance in feet below the ground surface.

SAMPLE: Sample Type as depicted above.

BLOW COUNT: Number of blows required to advance the sampler 12 inches using a 140 lb hammer with a 30-inch drop. 50/3" indicates penetration refusal (>50 blows) at 3 inches. WH indicates that the weight of the hammer was sufficient to push the sampler 6 inches or more.

POCKET PEN.: Approximate shear strength of a cohesive soil sample as measured by pocket penetrometer.

GRAPHIC LOG: Graphic Soil Symbol as depicted on the following page.

DRY DENSITY: Dry density of an undisturbed or relatively undisturbed sample in lbs/ft^3.

MOISTURE CONTENT: Moisture content of a soil sample, expressed as a percentage of the dry weight.

LIQUID LIMIT: The moisture content above which a soil behaves as a liquid.

PLASTIC LIMIT: The moisture content above which a soil behaves as a plastic.

PASSING #200 SIEVE: The percentage of the sample finer than the #200 standard sieve.

UNCONFINED SHEAR: The shear strength of a cohesive soil sample, as measured in the unconfined state.

INFILTRATION CALCULATIONS

Project Name	Proposed E-Commerce Development
Project Location	Beaumont, CA
Project Number	21G133-2
Engineer	Caleb Brackett

Test Hole Radius	4	(in)
Test Depth	22.00	(ft)

Infiltration Test Hole: I-1

Soil Criteria Test

Interval Number		Time	Time Interval (min)	Water Depth (ft)	Change in Water Level (in)	Did 6 inches of water seep away in less than 25 minutes?	Sandy Soils or Non-Sandy Soils?
1	Initial	11:00 AM	25.00	19.00	23.04	YES	SANDY SOILS
	Final	11:25 AM		20.92			
2	Initial	11:28 AM	25.00	19.00	23.16	YES	SANDY SOILS
	Final	11:53 AM		20.93			

Test Data

Interval Number		Time	Time Interval (min)	Water Depth (ft)	Change in Water Level (ft)	Average Head Height (ft)	Infiltration Rate Q (in/hr)
1	Initial	12:00 PM	10.00	19.00	0.90	2.55	3.98
	Final	12:10 PM		19.90			
2	Initial	12:11 PM	10.00	19.00	0.91	2.55	4.03
	Final	12:21 PM		19.91			
3	Initial	12:22 PM	10.00	19.00	0.90	2.55	3.98
	Final	12:32 PM		19.90			
4	Initial	12:33 PM	10.00	19.00	0.91	2.55	4.03
	Final	12:43 PM		19.91			
5	Initial	12:44 PM	10.00	19.00	0.90	2.55	3.98
	Final	12:54 PM		19.90			
6	Initial	12:55 PM	10.00	19.00	0.90	2.55	3.98
	Final	1:05 PM		19.90			

Per County Standards, Infiltration Rate calculated as follows:

$$Q = \frac{\Delta H(60r)}{\Delta t(r + 2H_{avg})}$$

Where:
- Q = Infiltration Rate (in inches per hour)
- ΔH = Change in Height (Water Level) over the time interval
- r = Test Hole (Borehole) Radius
- Δt = Time Interval
- H_{avg} = Average Head Height over the time interval

INFILTRATION CALCULATIONS

	Final	9:57 AM		22.67			

Per County Standards, Infiltration Rate calculated as follows:

$$Q = \frac{\Delta H(60r)}{\Delta t(r + 2H_{avg})}$$

Where:
- Q = Infiltration Rate (in inches per hour)
- ΔH = Change in Height (Water Level) over the time interval
- r = Test Hole (Borehole) Radius
- Δt = Time Interval
- H_{avg} = Average Head Height over the time interval

	Final	12:22 PM		42.40			

Per County Standards, Infiltration Rate calculated as follows:

$$Q = \frac{\Delta H(60r)}{\Delta t(r + 2H_{avg})}$$

Where:
- Q = Infiltration Rate (in inches per hour)
- ΔH = Change in Height (Water Level) over the time interval
- r = Test Hole (Borehole) Radius
- Δt = Time Interval
- H_{avg} = Average Head Height over the time interval

SECTION 1 - SUMMARY

PURPOSE

The purpose of this report is to document the hydrologic and hydraulic analyses performed in support of the Beaumont Summit Station (BSS) - Building 3 project located in the City of Beaumont, County of Riverside, California. The overall project site consists of approximately 188 acres of TPM 38223 which currently contains mostly vacant land with some pavement and structures and is bounded by Cherry Valley Boulevard to the north, Brookside Avenue to the south, residential lots to the east and vacant land to the west. TPM 38223 consists of approximately 145.4 acres of e-commerce, 11.4 acres of commercial, and 31.2 acres of open space areas. This report will focus on the BSS - Building 3 project, a proposed e-commerce development on approximately 20.7 acres of the northeast portion of the overall project area. The BSS – Building 3 project is bounded by Cherry Valley Boulevard to the north, the future BSS – Building 1 development to the west, vacant Parcel 4 of TPM 38223 to the east and the future BSS – Building 2 development to the south. This report will summarize the hydrologic and hydraulic analyses that were conducted in order to determine the necessary drainage improvements required to provide flood protection for the proposed building and safely convey the runoff through the site.

The scope of this report will include the following:

- Determine the peak 100-year and 10-year flow rates for the developed condition using the Riverside County Flood Control and Water Conservation District (RCFC&WCD) Rational Method.
- Determine the required storm drain facilities, alignment, and sizes required to flood protect the project site.
- Preparation of a preliminary report summarizing the hydrology and hydraulic results.

DESCRIPTION OF WATERSHED

As previously described, the project is proposing to build an e-commerce development of three warehouses on approximately 145.4 acres of vacant land with some pavement and structures. The BSS project is located within the Sunny Cal Specific Plan. Existing elevations across the site vary from 2554 to 2419 (NAVD88 datum). The slopes throughout the site vary, while the general existing drainage pattern for the site is characterized by sheet flow to the southwest. Along the southwestern boundary of the BSS project, an existing escarpment conveys runoff from the site into a vegetated streambed which runs northwest. A portion of the eastern and southern areas of the site drain south, where the streambed parallels Brookside Avenue. The majority of the site drains southwest into the same streambed, further downstream. A field survey was performed to determine the boundary of the project site in order to reduce the impacts on the existing vegetated streambed. The streambed eventually enters an existing concrete ditch along Calimesa Boulevard to the northwest of the project.

EXISTING CONDITIONS

The BSS – Building 3 project is a proposed e-commerce development on approximately 20.7 acres of vacant land within the boundaries of the overall BSS project boundary. Existing elevations across the site vary from 2554 to 2502 (NAVD88 datum). The area of the site currently slopes down at approximately 7% to southwest. The existing drainage pattern for the site and the general area is characterized by sheet flow to the southwest.

PROPOSED CONDITIONS

The overall project includes development of Buildings 1, 2, and 3 with mass grading of Parcel 4. Prior to the individual building developments, the overall BSS site will be mass graded. During mass grading, the backbone infrastructure will be constructed, including "A", "B", and "C" Streets and the emergency

access road along with associated utilities. After mass grading, the individual building sites will be developed separately. Each building will mitigate for increased runoff within its own site. Facilities proposed to mitigate for increased runoff will be constructed as part of the individual building developments.

In the Building 3 proposed condition, onsite runoff will be conveyed throughout the site via proposed ribbon gutters and curb and gutters. Onsite runoff will then be captured by a network of inlets provided at low points. Proposed underground storm drain conveys captured flows towards a proposed underground detention system. Due to the lack of downstream storm drain facilities, the project site will be required to mitigate for increases in runoff. The underground CMP detention chambers have been sized to mitigate for increased runoff for the 2-year, 5-year, 10-year and 100-year storm event with a duration of 24-hours. For preliminary purposes, it was assumed this will result in the largest mitigation volume required. Additional durations will be analyzed during final engineering. Further details on the mitigation for increased runoff for the overall BSS project may be found in the "Beaumont Summit Station Preliminary Drainage Study" (See Appendix D). An outlet structure from the detention system has been designed to achieve outflow that does not surpass the existing flowrates. The runoff will discharge from the detention system into a proposed storm drain line which will also collect the flows from Parcel 4 of TPM 38223. The proposed storm drain line will run south along the proposed access road, "B" Street, within the BSS project area and outlet into the existing vegetated streambed along the southern boundary of the BSS site. The streambed will convey runoff towards the northwest, following the existing drainage pattern. The relevant agencies do not have required setbacks or buffers for the stream that are globally set or dictated, but project design will be implemented to ensure the avoided jurisdictional features are not directly or indirectly impacted. Permits are in process to obtain approval with the relevant agencies. If necessary, modifications will be made through the permit processes and changes will be implemented in final design.

A bioretention basin is proposed to provide water quality treatment (additional information can be found in the separate Preliminary WQMP Report). The water quality flows will be pumped from the detention chambers to the basin in the northeast corner of the site. Treated flows are to be discharged into the proposed backbone storm drain line which receives the mitigated Building 3 flows.

Parcel 4 is proposed to be mass graded for future commercial development. A temporary desilting basin is to be graded, which will collect the runoff from Parcel 4 before it discharges into the proposed storm drain network in the BSS – Building 3 project site. A temporary outlet structure will be provided in order to prevent sediment, trash and debris from entering the proposed storm drain system. Parcel 4 has been included in the hydrologic analysis but will not be addressed in water quality calculations for the BSS – Building 3 project. Parcel 4 will require a separate water quality analysis once developed.

METHODOLOGY

HYDROLOGY

Hydrologic calculations were performed in accordance with the RCFC&WCD Hydrology Manual, dated April 1978. The Rational Method was utilized in determining peak flow rates.

The hydrological parameters, including rainfall values and soil types were derived from the RCFC&WCD Hydrology Manual. The isohyetal maps and soil map have been included in Section 2.

Rational Method calculations were performed using a computer program developed by CivilDesign Corporation and Joseph E. Bonadiman and Associates Inc. The computer program is commonly referred to as CivilD which incorporates the hydrological parameters outlined in the RCFC&WCD Hydrology Manual.

The Rational Method was used to determine the peak flow rates to size and design the drainage facilities need to convey onsite flows through the site to the proposed basin. The flow rates were computed by generating a hydrologic "link-node" model in which the overall area is divided into separate drainage sub-areas, each tributary to a concentration point (node) determined by the proposed layout and grading.

The Unit Hydrograph Method was used to determine the peak flow rates and volumes associated with the 2-year, 5-year,10-year, and 100-year storm events for the site. Calculations were performed for both the existing condition and developed condition to be used in the sizing of the CMP detention system. See "Beaumont Summit Station Preliminary Drainage Study" in Appendix C for additional information and results regarding the hydrologic analyses performed for this project.

HYDRAULICS

Water quality calculations were performed using spreadsheets that were created by RCFC&WCD. Final calculations and additional details can be found in the Preliminary-WQMP.

Hydraulic calculations to determine the required pipe sizes of proposed storm drain facilities will be provided in the Final Drainage Study.

SECTION 2 - HYDROLOGY ANALYSIS

HYDROLOGY PARAMETERS

The RCFC&WCD Hydrology Manual was used to determine several of the hydrological parameters. The following rainfall depths were utilized in the hydrology analyses, which were obtained from the NOAA Atlas 14:

Table 1 – Precipitation Values

	Duration
Storm Event	1-Hour (inches)
2-Year	0.581
100-Year	1.67

The NOAA Atlas 14 rainfall data can be found in Appendix A.

Based on the Plate C-1.18 (El Casco) in the RCFC&WCD Hydrology Manual, the project site is classified as soil type B and D. The soils map is included in Appendix A.

OVERALL SITE RATIONAL METHOD HYDROLOGY

The existing condition rational method was performed for the overall site for reference purposes. Mitigation of increased runoff for the developed condition is based on the unit hydrograph analysis for the 2-, 5-, 10- and 100-year storm events (See Section 4). The overall site was divided into two main areas. Approximately 106.4 areas of the north and west site are analyzed in the 700 series. Approximately 50.2 acres of the south and east site were analyzed in the 800 series. The undeveloped site primarily consists of undeveloped land with varying slopes. Therefore, it was analyzed as a natural channel type flow through the undeveloped sections. The site all drains to the existing streambed which runs to the west along the southern border of the site. The 700 series leaves the site at the western boundary while the 800 series discharges into the streambed area at the southern boundary of the site.

In the developed condition, approximately 1.5 acres between the northern BSS project boundary and proposed right-of-way are draining to Cherry Valley Boulevard. Approximately 9.5 acres of landscaped areas along the western boundary of the BSS – Building 1 site are to drain directly offsite to the west and south of the site, as in the existing condition. These approximately 11 acres were not accounted for in the developed condition rational method analysis and therefore create a difference in the total areas analyzed in the existing and developed conditions. These areas were analyzed in the unit hydrograph and routing calculations for mitigation of onsite flows.

ON-SITE RATIONAL METHOD HYDROLOGY

The rational method was used to determine peak flow rates in order to adequately size the proposed subsurface storm drains and associated inlets used to convey on-site flows to the proposed CMP detention system. Approximately 31.6 acres within the project area are tributary to the proposed storm drain facilities within the BSS – Building 3 project boundary. Approximately 20.7 acres of area consists of the onsite developments of the BSS – Building 3 project. The remaining 10.9 acres of area consists of Parcel 4, which connects to a proposed storm drain line within the BSS – Building 3 project. These areas

were broken up into two major areas (the 500-Series and the 600-Series) based on the locations of proposed inlets at low points throughout the site. Each series contains its own storm drain line which discharges into the chamber system at two inlets to the system. The subareas were further broken up into smaller areas in order to be modelled properly in the calculations. Most subareas consist of roof, landscaped areas, parking lots and drive aisles.

The 500-Series consists of approximately 10.8 acres of the northern and western project area. The 600-Series consists of approximately 19.3 acres of the eastern BSS – Building 3 project area and Parcel 4.

The following table summarizes the rational method results at key points:

Table 2 – Overall Project Watershed Rational Method Results

	Existing Condition			Developed Condition		
Point of Interest	**Area (ac)**	**Q_{10} (cfs)**	**Q_{100} (cfs)**	**Area (ac)**	**Q_{10} (cfs)**	**Q_{100} (cfs)**

Building 3 Detention Chambers Mitigated Outflow*	-	3.18	12.18

*See Section 4 for the routing analysis details

The rational method output files and hydrology map have been included in Appendix A.

OFF-SITE RATIONAL METHOD HYDROLOGY

All flows entering the proposed storm drains and associated inlets are generated on-site. Cross gutters are proposed along "A", "B" and "C" Streets to prevent runoff from Cherry Valley Boulevard from entering the site. Approximately 39.4 acres to the east of BSS - Building 2 and Parcel 4 produce runoff which would flow onsite. In the existing condition, flows from the offsite area would ultimately flow into the existing stream to the south of the BSS project site. A concrete channel is proposed with the mass grading and construction of backbone improvements to divert flows south towards the existing stream without impacting the project site (see the separate "Beaumont Summit Station - Building 2 Preliminary Drainage Study" for channel details). The offsite rational method analysis was performed for a total of 44.1 acres. This includes the area to the east of the project and 4.7 acres of the south of the BSS - Building 2 site which will be conveyed through a culvert across the emergency access road proposed to connect the BSS site to Brookside Avenue to the south. The following tables summarize the rational method results at key points:

Table 4 – Off-site Rational Method Results

Off-site Rational Method Point of Interest	Area (ac)	Q_{10} (cfs)	Q_{100} (cfs)
Node 3- Flows from Area East of Building 2 and Parcel 3	39.4	56.8	102.0
Node 4- Total Flows Entering Proposed Culvert	44.1	63.6	114.0

The rational method output files and hydrology map have been included in Appendix A.

SECTION 3 - HYDRAULIC ANALYSIS

ON-SITE STORM DRAIN FACILITIES

Storm drain facilities throughout the site have been preliminarily designed to convey the 100-year storm event based on the rational method analysis. Runoff generated onsite is conveyed via proposed curb and gutter and ribbon gutters towards proposed water quality treatment and mitigation systems. For the Buildings 3 site, a CMP detention system is proposed which will provide mitigation for increased runoff. Hydraulic analysis and sizing of the proposed storm drain lines are to be provided with the final engineering.

Building 3 - CMP Chambers

To mitigate for increased runoff within the BSS – Building 3 project site, a CMP detention system is proposed to hold 480,000 cubic ft of runoff. Two underground chamber systems are proposed to be connected by an equalizer pipe to achieve the required detention volume. The first chamber system, which is to hold 280,000 cubic ft, will consist of 4 barrels, which are 1004 ft long each. The second chamber system, which is to hold 200,000 cubic ft, will consist of 18 barrels which are 150 ft long each. The chambers are proposed to be perforated chambers with a liner installed between the chambers and soil below as a geotechnical investigation recommended no infiltration at this location of the site. The details of the CMP chamber sizing have been included in Appendix B.

An outlet structure is proposed to ensure outflow does not exceed existing flow rates for each storm event. The outlet structure is proposed to consist of an orifice with the invert at the bottom of the chambers to mitigate the peak flow rate of the 2-year storm event. Another orifice opening is proposed at the maximum ponding level of the 2-year storm event. This orifice serves to mitigate the 5-year storm event. At the maximum ponding depth of the 5-year storm event, a weir opening is proposed to mitigate the 10-year and 100-year peak flow rates. The mitigation of the storm events results in a maximum ponding depth of 7.03 ft, therefore the ponding remains within the top of the chambers. Additional information regarding these depths can be found in Section 4. A rip rap section is proposed at the outlet storm drain line of the chambers, sized per the Riverside County Standard Drawing No. 314. The lengths and thickness of the rip rap section are based on the pipe diameter and design velocity, respectively. A 14 ft long and 4.3 ft thick rip rap section of 1 ton rock with a 1 ft thick 1" crushed rock filter is proposed based on preliminary sizing.

The CMP chambers will receive the water quality flows via the proposed underground storm drain system. A pump is proposed to direct the water quality runoff volume directly to the proposed bioretention basin in the northeast portion of the site to be treated. Therefore, the chambers will not be required to detain the water quality volume and the chamber sizing is based only on the required mitigation volume for increased runoff.

OFF-SITE STORM DRAIN FACILITIES

Cutoff Channel

A concrete cutoff channel is proposed along the eastern boundary of the BSS project site to divert flows generated on approximately 39.4 acres east of the BSS – Building 2 and Parcel 4 site towards the existing stream to the south. The channel is proposed to be 6 ft wide with 2:1 side slopes and will have a depth of 1.1 ft to convey the 100-year peak flow rate of 102 cfs. The hydraulic model for the channel is included in Appendix B. The cutoff channel is proposed to be constructed with the mass grading and backbone infrastructure of the overall BSS site and is to remain with future development of the Building 2 and Parcel 4 sites to prevent offsite flows from impacting the BSS site.

Emergency Access Road Culvert

A culvert is proposed south of the BSS – Building 2 site to convey flows across the proposed emergency access road which provides access from Brookside Avenue to the BSS project site. The culvert is a proposed 36" storm drain line which has been sized to convey the 100-year peak flow rate of 114 cfs across the access road to the existing stream. The rip rap section at the outlet of the culvert has been sized per the Riverside County Standard Drawing No. 314. The lengths and thickness of the rip rap section are based on the pipe diameter and design velocity, respectively. A 12 ft long and 5.4 ft thick rip rap section of 2 ton rock with a 1 ft thick 1" crushed rock filter layer is proposed based on preliminary culvert sizing. The hydraulic model for the culvert is included in Appendix B.

SECTION 4 - BASIN ANALYSIS

HYDROLOGY PARAMETERS

The RCFC&WCD Hydrology Manual was used to determine several of the hydrological parameters. The following rainfall depths were utilized in the hydrology analyses, which were obtained from the isohyetal maps provided in the RCFC&WCD Hydrology Manual:

Table 1 – Precipitation Values

	Duration			
Storm Event	1-Hour (inches)	3-Hour (inches)	6-Hour (inches)	24-Hour (inches)
2-Year	0.55	0.95	1.40	2.50
100-Year	1.25	2.05	3.00	6.50

The value for slope of intensity was determined to be 0.53. The isohyetal maps have been included in Appendix A.

Based on the Plate C-1.18 (El Casco) in the RCFC&WCD Hydrology Manual, the project site is classified as soil types B and D. The soils map is included in Appendix A.

The cover type was determined based on the existing land cover and proposed land use of the site. Hydrological computations for the existing condition were done using Natural Grass and Residential or Commercial. The Urban or Residential or Commercial cover type was used to represent the developed condition. The table below summarizes the runoff index values and the recommended values for percentage of impervious cover for each category:

Table 2 – Cover Type

Cover Type	Soil Group A	Soil Group B	Soil Group C	Soil Group D	Percentage of Impervious Cover
Existing Condition Natural Grass	-	78	-	89	12.0% (Area A) 33.0% (Area B)
Existing Residential or Commercial	-	56	-	75	
Developed Urban Residential or Commercial – Building 3	-	56	-	75	76.0%

ON-SITE UNIT HYDROGRAPH METHOD HYDROLOGY

The unit hydrograph method was used to determine the peak flow rates and volumes in order to adequately size the proposed chamber detention system to address increased runoff mitigation. Unit hydrographs were performed for both the 24-hour existing condition and developed condition only in the preliminary condition since it was assumed that the 24-hour condition will require the greatest mitigation volume. The existing condition is used to establish a baseline for comparative purposes. The developed condition is used for design purposes, it was utilized in the basin routing analysis in order to size and analyze the proposed CMP chamber detention system. The unit hydrograph analysis for both the existing

and developed condition was conducted for a total of 156.8 acres. This comprises the entirety of the proposed development with the BSS project site.

In the existing condition analysis, the overall project site was broken up into two areas. Approximately 106.4 acres are labelled as Area A (700-Series in the rational method analysis) and is tributary to the existing streambed area to the west of the project site. The remaining 50.4 acres are labelled as Area B (800-Series) and are tributary to a region of the streambed to the south of the project site. In the proposed condition, Area A is divided into a West Area and North Area (corresponding to Building 1 and Building 3, respectively). The West Area consists of approximately 55.3 acres while the North area is approximately 33.8 acres. In the developed condition, approximately 17.4 acres of area which was tributary to Area A in the existing condition have been included in the development of the South Area (part of the existing condition Area B). Therefore, the developed South Area will be over mitigating for flows as a greater area, and therefore greater discharge, is included in the developed condition analysis. While the existing condition Area A will be under mitigated once developed, the overall BSS site will be mass graded together as grading will require cut from the Building 2 area, in Area B, to be used in fill for mass grading of the Building 1 project site. Therefore, overall the BSS project will be fully mitigated once developed.

The following table summarizes the results of the unit hydrograph analysis:

Table 4 – Unit Hydrograph Results

EXISTING CONDITION - AREA A (WEST & NORTH)					DEVELOPED CONDITION - NORTH				
AREA	RETURN PERIOD (yr)	EVENT (hrs)	VOL (ac-ft)	PEAK (cfs)	AREA	RETURN PERIOD (yr)	EVENT (hrs)	VOL (ac-ft)	PEAK (cfs)

The unit hydrograph output files and hydrology map have been included in Appendix C.

BASIN ROUTING ANALYSIS

A routing analysis was completed to demonstrate that the CMP chamber system contain substantial volume needed to mitigate flows down to existing condition peak flow rates.

Basin routing calculations were conducted for each building area (west, north and south). A stage-storage-discharge table was determined for each area. The stage-storage-discharge tables provide input data at select elevations in the basin and/or chambers which will determine the storage and discharge at each point based on the mitigation configuration of the outlet structures.

In the existing condition, the entire Area A generally drains to the southwest. Approximately 16.6% of Area A drains more towards the southern boundary before being conveyed to the west along the streambed. This area corresponds to the developed North Area (Building 3). For the developed condition West Area and North Area, a ratio of the areas was used to determine the existing peak flow rates which serve as the limits for the routing analysis of each area. An exhibit showing the portion of the existing condition Area A which flows south can be found in Appendix C.

For the BSS- Building 3 area, the proposed outlet structure consists of a 3.5-inch orifice plate with an invert set at the bottom of the chambers. The water quality flows will be pumped out to be treated by the proposed bioretention basin therefore the chambers do not hold the water quality volume. This orifice mitigates the 2-year storm event. A 5-inch orifice is proposed at the maximum ponding depth for the 2-year, 24-hour storm (a depth of approximately 3.49 ft). This orifice mitigates for the 5-year storm event and creates a maximum ponding depth of 4.46 ft within the chambers. At this depth, a 0.8 ft weir is proposed to mitigate for the 10-year and 100-year storm events. The 10-year, 24-hour storm event creates a maximum ponding of 5.16 ft while the 100-year storm creates a maximum ponding of 7.03 ft, which is below 9 ft depth of the top of the gravel which provides storage above the chambers as well. The routing analysis for the BSS – Building 3 detention chambers resulted in a maximum drawdown time of approximately 228 hours. While this exceeds the 72-hour limit for above ground basins to prevent vector issues the CMP detention system consists of underground chambers and therefore vector issues are not anticipated even with a high drawdown time. This is due to this area over mitigating as the developed Building 3 project area is larger than the portion of the existing condition Area A which is used as the limit for the routing analysis of this region. While the mitigation for both Building 3 and Parcel 4 are included in the BSS – Building 3 Area, Parcel 4 will be required to treat for water quality separately from Building 3.

The following tables present the result of routing analysis for the 2-, 5-, 10- and 100-year, 24-hour storm events to demonstrate that the CMP chamber system provides the necessary storage volume needed to restrict the outflow to existing condition flow rates.

The basin routing calculations and other hydraulic calculations have been provided in Appendix C. Based on the table below, the proposed detention chambers for the BSS - Building 3 area have the capacity to mitigate for all the required HCOC and RCFC&WCD storm events. All discharge flow rates in the developed condition are lower than or within ten percent of the flow rate exiting the site in the existing condition.

Table 5 – Basin Routing Results

Storm Event		Existing Condition				Developed Condition						Basin Routing Results		
		Area A (106.4 ac)		83.4% A	16.6% A	**West Area (55.3 ac)		North Area (33.8 ac)		Combined (89.1 ac)		**West Area	North Area	Combined

Note: ** The Combined Peak Flow describes the flows exiting the site along the western and southwestern boundary of the site. This value is the sum of the peak flow rates generated by the West and North Areas in the proposed condition which have been routed to be less than the existing condition peak flow for Area A or within 10% of this value.*

*** The West Area unit hydrograph and routing results have been included in Appendix D for reference. See the separate "Beaumont Summit Station – Building 1 Preliminary Drainage Study" for a detailed discussion and analysis of the West Area.*

SECTION 5 - CONCLUSION

Based on the analyses and results of this report, the following conclusions were derived from the hydrology and hydraulic results:

- The proposed drainage improvements will adequately convey flows to the basin and provide flood protection for the 100-year storm event.
- The proposed bioretention basin will provide adequate water quality treatment.
- The proposed project will not impact flooding condition to upstream or downstream properties.

[1] Precipitation frequency (PF) estimates in this table are based on frequency analysis of partial duration series (PDS).

Numbers in parenthesis are PF estimates at lower and upper bounds of the 90% confidence interval. The probability that precipitation frequency estimates (for a given duration and average recurrence interval) will be greater than the upper bound (or less than the lower bound) is 5%. Estimates at upper bounds are not checked against probable maximum precipitation (PMP) estimates and may be higher than currently valid PMP values.

Rational Method Hydrology Program based on
Riverside County Flood Control & Water Conservation District
1978 hydrology manual

Storm event (year) = 100.00 Antecedent Moisture Condition = 2

2 year, 1 hour precipitation = 0.581(In.)
100 year, 1 hour precipitation = 1.670(In.)

Storm event year = 100.0
Calculated rainfall intensity data:
1 hour intensity = 1.670(In/Hr)
Slope of intensity duration curve = 0.5300

++
Process from Point/Station 1.000 to Point/Station 2.000
**** INITIAL AREA EVALUATION ****

Initial area flow distance = 990.000(Ft.)
Top (of initial area) elevation = 2603.100(Ft.)
Bottom (of initial area) elevation = 2560.000(Ft.)
Difference in elevation = 43.100(Ft.)
Slope = 0.04354 s(percent)= 4.35
TC = k(0.480)*[(length^3)/(elevation change)]^0.2
Initial area time of concentration = 14.182 min.
Rainfall intensity = 3.587(In/Hr) for a 100.0 year storm
SINGLE FAMILY (1 Acre Lot)
Runoff Coefficient = 0.737
Decimal fraction soil group A = 0.000
Decimal fraction soil group B = 1.000
Decimal fraction soil group C = 0.000
Decimal fraction soil group D = 0.000
RI index for soil(AMC 2) = 56.00
Pervious area fraction = 0.800; Impervious fraction = 0.200
Initial subarea runoff = 15.338(CFS)
Total initial stream area = 5.800(Ac.)
Pervious area fraction = 0.800

++
Process from Point/Station 2.000 to Point/Station 3.000
**** IMPROVED CHANNEL TRAVEL TIME ****

Upstream point elevation = 2560.000(Ft.)
Downstream point elevation = 2535.000(Ft.)
Channel length thru subarea = 1175.000(Ft.)
Channel base width = 6.000(Ft.)
Slope or 'Z' of left channel bank = 2.000
Slope or 'Z' of right channel bank = 2.000
Estimated mean flow rate at midpoint of channel = 58.684(CFS)

```
Manning's 'N'    = 0.015
Maximum depth of channel  =    2.500(Ft.)
Flow(q) thru subarea =     58.684(CFS)
Depth of flow =   0.756(Ft.), Average velocity =  10.339(Ft/s)
Channel flow top width =    9.023(Ft.)
Flow Velocity =   10.34(Ft/s)
Travel time  =    1.89 min.
Time of concentration =   16.08 min.

Sub-Channel No. 1 Critical depth =      1.250(Ft.)
  '     '       '     Critical flow top width =     11.000(Ft.)
  '     '       '     Critical flow velocity=    5.523(Ft/s)
  '     '       '     Critical flow area =     10.625(Sq.Ft)

 Adding area flow to channel
USER INPUT of soil data for subarea
Runoff Coefficient = 0.768
Decimal fraction soil group A = 0.000
Decimal fraction soil group B = 0.970
Decimal fraction soil group C = 0.000
Decimal fraction soil group D = 0.030
RI index for soil(AMC 2)  =  67.70
Pervious area fraction =  0.920; Impervious fraction =  0.080
Rainfall intensity =      3.356(In/Hr) for a   100.0 year storm
Subarea runoff =     86.617(CFS) for     33.600(Ac.)
Total runoff =    101.955(CFS)       Total area =      39.400(Ac.)
Depth of flow =   1.030(Ft.), Average velocity =  12.275(Ft/s)

Sub-Channel No. 1 Critical depth =      1.703(Ft.)
  '     '       '     Critical flow top width =     12.813(Ft.)
  '     '       '     Critical flow velocity=    6.364(Ft/s)
  '     '       '     Critical flow area =     16.020(Sq.Ft)

++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++++
Process from Point/Station        3.000 to Point/Station        4.000
**** NATURAL CHANNEL TIME + SUBAREA FLOW ADDITION ****
________________________________________________________________________
Top of natural channel elevation =   2535.000(Ft.)
End of natural channel elevation =   2495.040(Ft.)
Length of natural channel  =   800.000(Ft.)
Estimated mean flow rate at midpoint of channel =    108.036(CFS)

Natural mountain channel type used
L.A. County flood control district formula for channel velocity:
 Velocity = 5.48(q^.33)(slope^.492)
Velocity using mean channel flow =   5.88(Ft/s)

Correction to map slope used on extremely rugged channels with
drops and waterfalls (Plate D-6.2)
       Normal channel slope =  0.0500
Corrected/adjusted channel slope =  0.0500
Travel time =    2.27 min.     TC =   18.34  min.

 Adding area flow to channel
UNDEVELOPED (fair cover) subarea
Runoff Coefficient = 0.818
Decimal fraction soil group A = 0.000
Decimal fraction soil group B = 0.200
Decimal fraction soil group C = 0.000
Decimal fraction soil group D = 0.800
RI index for soil(AMC 2)  =  81.00
Pervious area fraction =  1.000; Impervious fraction =  0.000
Rainfall intensity =      3.130(In/Hr) for a   100.0 year storm
Subarea runoff =     12.036(CFS) for      4.700(Ac.)
Total runoff =    113.991(CFS)       Total area =      44.100(Ac.)

Hydraulic Analysis Report

Project Data

Project Title:

Designer:

Project Date: Thursday, February 17, 2022

Project Units: U.S. Customary Units

Notes:

Channel Analysis: Cutoff Channel

Notes:

Input Parameters

Channel Type: Trapezoidal

Side Slope 1 (Z1): 2.0000 ft/ft

Side Slope 2 (Z2): 2.0000 ft/ft

Channel Width: 6.0000 ft

Longitudinal Slope: 0.0150 ft/ft

Manning's n: 0.0150

Flow: 102.0000 cfs

Result Parameters

Depth: 1.1354 ft

Area of Flow: 9.3909 ft^2

Wetted Perimeter: 11.0778 ft

Hydraulic Radius: 0.8477 ft

Average Velocity: 10.8616 ft/s

Top Width: 10.5417 ft

Froude Number: 2.0280

Critical Depth: 1.7062 ft

Critical Velocity: 6.3512 ft/s

Critical Slope: 0.0033 ft/ft

Critical Top Width: 12.82 ft

Calculated Max Shear Stress: 1.0628 lb/ft^2

Calculated Avg Shear Stress: 0.7935 lb/ft^2

Drainage Area = 106.40(Ac.) = 0.166 Sq. Mi.
Drainage Area for Depth-Area Areal Adjustment = 106.40(Ac.) = 0.166 Sq. Mi.
Length along longest watercourse = 3950.00(Ft.)
Length along longest watercourse measured to centroid = 1805.00(Ft.)
Length along longest watercourse = 0.748 Mi.
Length along longest watercourse measured to centroid = 0.342 Mi.
Difference in elevation = 162.00(Ft.)
Slope along watercourse = 216.5468 Ft./Mi.
Average Manning's 'N' = 0.030
Lag time = 0.154 Hr.
Lag time = 9.26 Min.
25% of lag time = 2.32 Min.
40% of lag time = 3.70 Min.
Unit time = 5.00 Min.
Duration of storm = 24 Hour(s)
User Entered Base Flow = 0.00(CFS)

2 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
106.40	1.50	159.60

100 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
106.40	6.50	691.60

STORM EVENT (YEAR) = 2.00
Area Averaged 2-Year Rainfall = 1.500(In)
Area Averaged 100-Year Rainfall = 6.500(In)

Point rain (area averaged) = 1.500(In)
Areal adjustment factor = 99.98 %
Adjusted average point rain = 1.500(In)

Sub-Area Data:

Area(Ac.)	Runoff Index	Impervious %
106.400	77.30	0.120

Total Area Entered = 106.40(Ac.)

RI AMC2	RI AMC-1	Infil. Rate (In/Hr)	Impervious (Dec.%)	Adj. Infil. Rate (In/Hr)	Area% (Dec.)	F (In/Hr)

77.3	59.8	0.472	0.120	0.421	1.000	0.421
					Sum (F) =	0.421

Area averaged mean soil loss (F) (In/Hr) = 0.421
Minimum soil loss rate ((In/Hr)) = 0.211
(for 24 hour storm duration)
Soil low loss rate (decimal) = 0.800

Drainage Area = 106.40(Ac.) = 0.166 Sq. Mi.
Drainage Area for Depth-Area Areal Adjustment = 106.40(Ac.) = 0.166 Sq. Mi.
Length along longest watercourse = 3950.00(Ft.)
Length along longest watercourse measured to centroid = 1805.00(Ft.)
Length along longest watercourse = 0.748 Mi.
Length along longest watercourse measured to centroid = 0.342 Mi.
Difference in elevation = 162.00(Ft.)
Slope along watercourse = 216.5468 Ft./Mi.
Average Manning's 'N' = 0.030
Lag time = 0.154 Hr.
Lag time = 9.26 Min.
25% of lag time = 2.32 Min.
40% of lag time = 3.70 Min.
Unit time = 5.00 Min.
Duration of storm = 6 Hour(s)
User Entered Base Flow = 0.00(CFS)

2 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
106.40	1.40	148.96

100 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
106.40	3.00	319.20

STORM EVENT (YEAR) = 10.00
Area Averaged 2-Year Rainfall = 1.400(In)
Area Averaged 100-Year Rainfall = 3.000(In)

Point rain (area averaged) = 2.058(In)
Areal adjustment factor = 99.96 %
Adjusted average point rain = 2.058(In)

Sub-Area Data:

Area(Ac.)	Runoff Index	Impervious %
106.400	77.30	0.120

Total Area Entered = 106.40(Ac.)

RI AMC2	RI AMC-2	Infil. Rate (In/Hr)	Impervious (Dec.%)	Adj. Infil. Rate (In/Hr)	Area% (Dec.)	F (In/Hr)

77.3	77.3	0.276	0.120	0.246	1.000	0.246
					Sum (F) =	0.246

Area averaged mean soil loss (F) (In/Hr) = 0.246
Minimum soil loss rate ((In/Hr)) = 0.123
(for 24 hour storm duration)
Soil low loss rate (decimal) = 0.800

Program License Serial Number 4010

English (in-lb) Input Units Used
English Rainfall Data (Inches) Input Values Used

English Units used in output format

EXETER AREA A EXISTING CONDITION
10-YEAR STORM EVENT
21-0044 EXETER INDUSTRIAL
07-19-2021 EP

Drainage Area = 106.40(Ac.) = 0.166 Sq. Mi.
Drainage Area for Depth-Area Areal Adjustment = 106.40(Ac.) = 0.166 Sq. Mi.
Length along longest watercourse = 3950.00(Ft.)
Length along longest watercourse measured to centroid = 1805.00(Ft.)
Length along longest watercourse = 0.748 Mi.
Length along longest watercourse measured to centroid = 0.342 Mi.
Difference in elevation = 162.00(Ft.)
Slope along watercourse = 216.5468 Ft./Mi.
Average Manning's 'N' = 0.030
Lag time = 0.154 Hr.
Lag time = 9.26 Min.
25% of lag time = 2.32 Min.
40% of lag time = 3.70 Min.
Unit time = 5.00 Min.
Duration of storm = 24 Hour(s)
User Entered Base Flow = 0.00(CFS)

2 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
106.40	2.50	266.00

100 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
106.40	6.50	691.60

STORM EVENT (YEAR) = 10.00
Area Averaged 2-Year Rainfall = 2.500(In)
Area Averaged 100-Year Rainfall = 6.500(In)

Point rain (area averaged) = 4.146(In)
Areal adjustment factor = 99.98 %
Adjusted average point rain = 4.145(In)

Sub-Area Data:

Area(Ac.)	Runoff Index	Impervious %
106.400	77.30	0.120

Total Area Entered = 106.40(Ac.)

RI AMC2	RI AMC-2	Infil. Rate (In/Hr)	Impervious (Dec.%)	Adj. Infil. Rate (In/Hr)	Area% (Dec.)	F (In/Hr)

77.3	77.3	0.276	0.120	0.246	1.000	0.246
					Sum (F) =	0.246

Area averaged mean soil loss (F) (In/Hr) = 0.246
Minimum soil loss rate ((In/Hr)) = 0.123
(for 24 hour storm duration)
Soil low loss rate (decimal) = 0.800

English (in-lb) Input Units Used
English Rainfall Data (Inches) Input Values Used

English Units used in output format

EXETER NORTH DEVELOPED CONDITION
2-YEAR STORM EVENT
21-0044 EXETER INDUSTRIAL
2021-07-20 EP

Drainage Area = 33.80(Ac.) = 0.053 Sq. Mi.
Drainage Area for Depth-Area Areal Adjustment = 33.80(Ac.) = 0.053 Sq. Mi.
Length along longest watercourse = 3290.00(Ft.)
Length along longest watercourse measured to centroid = 2480.00(Ft.)
Length along longest watercourse = 0.623 Mi.
Length along longest watercourse measured to centroid = 0.470 Mi.
Difference in elevation = 86.20(Ft.)
Slope along watercourse = 138.3392 Ft./Mi.
Average Manning's 'N' = 0.015
Lag time = 0.088 Hr.
Lag time = 5.31 Min.
25% of lag time = 1.33 Min.
40% of lag time = 2.12 Min.
Unit time = 5.00 Min.
Duration of storm = 24 Hour(s)
User Entered Base Flow = 0.00(CFS)

2 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
33.80	2.50	84.50

100 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
33.80	6.50	219.70

STORM EVENT (YEAR) = 2.00
Area Averaged 2-Year Rainfall = 2.500(In)
Area Averaged 100-Year Rainfall = 6.500(In)

Point rain (area averaged) = 2.500(In)
Areal adjustment factor = 99.99 %
Adjusted average point rain = 2.500(In)

Sub-Area Data:

Area(Ac.)	Runoff Index	Impervious %
33.800	56.00	0.760

Total Area Entered = 33.80(Ac.)

RI AMC2	RI AMC-1	Infil. Rate (In/Hr)	Impervious (Dec.%)	Adj. Infil. Rate (In/Hr)	Area% (Dec.)	F (In/Hr)

56.0	36.0	0.706	0.760	0.223	1.000	0.223
					Sum (F) =	0.223

Area averaged mean soil loss (F) (In/Hr) = 0.223
Minimum soil loss rate ((In/Hr)) = 0.112
(for 24 hour storm duration)
Soil low loss rate (decimal) = 0.290

Drainage Area = 33.80(Ac.) = 0.053 Sq. Mi.
Drainage Area for Depth-Area Areal Adjustment = 33.80(Ac.) = 0.053 Sq. Mi.
Length along longest watercourse = 3290.00(Ft.)
Length along longest watercourse measured to centroid = 2480.00(Ft.)
Length along longest watercourse = 0.623 Mi.
Length along longest watercourse measured to centroid = 0.470 Mi.
Difference in elevation = 86.20(Ft.)
Slope along watercourse = 138.3392 Ft./Mi.
Average Manning's 'N' = 0.015
Lag time = 0.088 Hr.
Lag time = 5.31 Min.
25% of lag time = 1.33 Min.
40% of lag time = 2.12 Min.
Unit time = 5.00 Min.
Duration of storm = 24 Hour(s)
User Entered Base Flow = 0.00(CFS)

2 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
33.80	2.50	84.50

100 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
33.80	6.50	219.70

STORM EVENT (YEAR) = 100.00
Area Averaged 2-Year Rainfall = 2.500(In)
Area Averaged 100-Year Rainfall = 6.500(In)

Point rain (area averaged) = 6.500(In)
Areal adjustment factor = 99.99 %
Adjusted average point rain = 6.500(In)

Sub-Area Data:

Area(Ac.)	Runoff Index	Impervious %
33.800	56.00	0.760

Total Area Entered = 33.80(Ac.)

RI AMC2	RI AMC-2	Infil. Rate (In/Hr)	Impervious (Dec.%)	Adj. Infil. Rate (In/Hr)	Area% (Dec.)	F (In/Hr)

56.0	56.0	0.511	0.760	0.161	1.000	0.161
					Sum (F) =	0.161

Area averaged mean soil loss (F) (In/Hr) = 0.161
Minimum soil loss rate ((In/Hr)) = 0.081
(for 24 hour storm duration)
Soil low loss rate (decimal) = 0.290

RELEVANT EXCERPTS FROM "BEAUMONT SUMMIT STATION PRELIMINARY DRAINAGE STUDY"

SECTION 4 - BASIN ANALYSIS

ON-SITE UNIT HYDROGRAPH METHOD HYDROLOGY

The unit hydrograph method was used to determine the peak flow rates and volumes in order to adequately size the proposed basin and chamber detention systems to address increased runoff mitigation. Unit hydrographs were performed for both the 24-hour existing condition and developed condition only in the preliminary condition since it was assumed that the 24-hour condition will require the greatest mitigation volume. The existing condition is used to establish a baseline for comparative purposes. The developed condition is used for design purposes, it was utilized in the basin routing analysis in order to size and analyze the proposed basin and chamber detention systems. The unit hydrograph analysis for both the existing and developed condition was conducted for a total of 156.8 acres. This comprises the entirety of the proposed development with the BSS project site.

In the existing condition analysis, the overall project site was broken up into two areas. Approximately 106.4 acres are labelled as Area A and is tributary to the existing streambed area to the west of the project site. The remaining 50.4 acres are labelled as Area B and are tributary to a region of the streambed to the south of the project site. In the proposed condition, Area A is divided into a West Area and North Area (corresponding to Building 1 and Building 3, respectively). The West Area consists of approximately 55.3 acres while the North area is approximately 33.8 acres. Area B is referred to as the South Area in the developed condition and corresponds to the Building 2 project site, consisting of approximately 67.8 acres. In the developed condition, approximately 17.4 acres of area which was tributary to Area A in the existing condition have been included in the development of the South Area (part of the existing condition Area B). Therefore, the developed South Area will be over mitigating for flows as a greater area, and therefore greater discharge, is included in the developed condition analysis. While the existing condition Area A will be under mitigated once developed, the overall BSS site will be mass graded together as grading will require cut from the Building 2 area, in Area B, to be used in fill for mass grading of the Building 1 project site. Therefore, overall the BSS project will be fully mitigated once developed.

The following table summarizes the results of the unit hydrograph analysis:

Table 4 – Unit Hydrograph Results

The unit hydrograph output files and hydrology map have been included in Appendix C.

BASIN ROUTING ANALYSIS

A routing analysis was completed to demonstrate that the basin and CMP chamber systems contain substantial volume needed to mitigate flows down to existing condition peak flow rates.

Basin routing calculations were conducted for each building area (west, north and south). A stage-storage-discharge table was determined for each area. The stage-storage-discharge tables provide input data at select elevations in the basin and/or chambers which will determine the storage and discharge at each point based on the mitigation configuration of the outlet structures.

In the proposed condition unit hydrograph analysis, the North Area outlets to the south of the Building 1 project site. Runoff from this region will connect with the outlet of the existing condition Area A, as the streambed into which Area A outlets runs from the southern portion of the Building 1 project area to the northwest along the western boundary. In the existing condition, the entire Area A generally drains to the southwest. Approximately 16.6% of Area A drains more towards the southern boundary before being conveyed to the west along the streambed. This area corresponds to the developed North Area (Building 3). The remaining portion, approximately 83.4%, correlates to the developed West Area (Building 1) and drains directly to the western boundary of Area A. For the developed condition West Area and North Area, a ratio of the areas was used to determine the existing peak flow rates which serve as the limits for the routing analysis of each area. An exhibit showing the portion of the existing condition Area A which flows south can be found in Appendix C.

For the BSS – Building 1 area, the proposed outlet structure consists of four 4-inch orifices with an invert set at the water quality ponding elevation of 2.4 ft above the chamber bottom. This orifice mitigates the 2-year storm event. A 1.5-ft weir is proposed at the maximum ponding depth for the 2-year, 24-hour storm (a depth of approximately 5.82 ft). This orifice mitigates for the 5-year storm event and creates a maximum ponding depth of 6.96 ft above the chamber bottom. At the 5-year ponding depth, a 7-ft weir is proposed to mitigate the 10-year and 100-year storm event. The 100-year storm produces a maximum ponding of 7.99 ft, which is below the 8 ft depth of the top of the chambers. The routing analysis produced a maximum drawdown time of 88.6 hours within the chambers. While this exceeds the 72-hour limit for above ground basins to prevent vector issues, the CMP detention system consists of underground chambers and therefore vector issues are not anticipated even with a high drawdown time.

For the BSS – Building 2 area, a constant flow rate of 9.4 cfs was assumed for the basin in order to account for the expected infiltration within the basin extents. This value was determined based on a recommended infiltration rate of 11.5 in/hr within the basin (see Appendix D for the infiltration report), the bottom basin area, and a factor of safety of 3. The water quality volume produces a maximum ponding of 1.4 ft above the basin bottom. Routing of the 2-year, 24-hour storm event shows that the infiltration within the basin is sufficient to meet the existing condition flow rates while producing 2.15 ft of ponding above the basin bottom. The proposed outlet structure consists of a rectangular weir with a length of 6 ft set at the 2-year storm ponding depth. This weir mitigates the 5-year storm event and produces a ponding depth of 2.67 ft. A 6-ft weir mitigates for the 10-year storm event and creates a maximum ponding depth of 2.98 ft within the basin. At the 10-year ponding elevation, a 6-ft weir mitigates for the 100-year storm. The 100-year storm creates a total ponding of 3.36 ft from the basin bottom, allowing at least 1 ft of freeboard below the top of the basin.

For the BSS- Building 3 area, the proposed outlet structure consists of a 3.5-inch orifice plate with an invert set at the bottom of the chambers. The water quality flows will be pumped out to be treated by the proposed bioretention basin therefore the chambers do not hold the water quality volume. This orifice mitigates the 2-year storm event. A 5-inch orifice is proposed at the maximum ponding depth for the 2-year, 24-hour storm (a depth of approximately 3.49 ft). This orifice mitigates for the 5-year storm event and creates a maximum ponding depth of 4.46 ft within the chambers. At this depth, a 0.8 ft weir is proposed to mitigate for the 10-year and 100-year storm events. The 10-year, 24-hour storm event creates

a maximum ponding of 5.16 ft while the 100-year storm creates a maximum ponding of 7.03 ft, which is below 9 ft depth of the top of the gravel which provides storage above the chambers as well. The routing analysis for the BSS – Building 3 detention chambers resulted in a maximum drawdown time of approximately 228 hours. While this exceeds the 72-hour limit for above ground basins to prevent vector issues the CMP detention system consists of underground chambers and therefore vector issues are not anticipated even with a high drawdown time. This is due to this area over mitigating as the developed Building 3 project area is larger than the portion of the existing condition Area A which is used as the limit for the routing analysis of this region. While the mitigation for both Building 3 and Parcel 4 are included in the BSS – Building 3 Area, Parcel 4 will be required to treat for water quality separately from Building 3.

The following tables present the result of routing analysis for the 2-, 5-, 10- and 100-year 24-hour storm events to demonstrate that the basin and CMP chamber systems provide the necessary storage volume needed to restrict the outflow to existing condition flow rates.

Table 5 – Basin Routing Results

		Existing Condition

Note:

**The Combined Peak Flow describes the flows exiting the site along the western and southwestern boundary of the site. This value is the sum of the peak flow rates generated by the West and North Areas in the proposed condition which have been routed to be less than the existing condition peak flow for Area A or within 10% of this value.*

***For the routing analysis of the South Area (Building 2), a constant flow rate of 9.4 cfs is assumed to be infiltrating within the basin extents (based on 11.5 in/hr infiltration rate, the basin bottom area, and a factor of safety of 3) and has been subtracted from the peak flow results from the routing analysis.*

The basin routing calculations and other hydraulic calculations have been provided in Appendix C. Based on the table above, the proposed infiltration basin and detention chambers for each building area have the capacity to mitigate for all the required HCOC storm events. All discharge flow rates in the developed condition are lower than or within ten percent of the flow rate exiting the site in the existing condition.

EXETER WEST PROPOSED CONDITION
5-YEAR STORM EVENT
21-0044 EXETER INDUSTRIAL
2021-07-20 EP

Drainage Area = 55.30(Ac.) = 0.086 Sq. Mi.
Drainage Area for Depth-Area Areal Adjustment = 55.30(Ac.) = 0.086 Sq. Mi.
Length along longest watercourse = 2375.00(Ft.)
Length along longest watercourse measured to centroid = 1715.00(Ft.)
Length along longest watercourse = 0.450 Mi.
Length along longest watercourse measured to centroid = 0.325 Mi.
Difference in elevation = 88.00(Ft.)
Slope along watercourse = 195.6379 Ft./Mi.
Average Manning's 'N' = 0.015
Lag time = 0.064 Hr.
Lag time = 3.82 Min.
25% of lag time = 0.95 Min.
40% of lag time = 1.53 Min.
Unit time = 5.00 Min.
Duration of storm = 6 Hour(s)
User Entered Base Flow = 0.00(CFS)

2 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
55.30	1.40	77.42

100 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
55.30	3.00	165.90

STORM EVENT (YEAR) = 5.00
Area Averaged 2-Year Rainfall = 1.400(In)
Area Averaged 100-Year Rainfall = 3.000(In)

Point rain (area averaged) = 1.775(In)
Areal adjustment factor = 99.98 %
Adjusted average point rain = 1.774(In)

Sub-Area Data:

Area(Ac.)	Runoff Index	Impervious %
55.300	62.60	0.710

Total Area Entered = 55.30(Ac.)

RI AMC2	RI AMC-1	Infil. Rate (In/Hr)	Impervious (Dec.%)	Adj. Infil. Rate (In/Hr)	Area% (Dec.)	F (In/Hr)

62.6	42.6	0.645	0.710	0.233	1.000	0.233
					Sum (F) =	0.233

Area averaged mean soil loss (F) (In/Hr) = 0.233
Minimum soil loss rate ((In/Hr)) = 0.116
(for 24 hour storm duration)
Soil low loss rate (decimal) = 0.330

EXETER WEST PROPOSED CONDITION
5-YEAR STORM EVENT
21-0044 EXETER INDUSTRIAL
2021-07-20 EP

Drainage Area = 55.30(Ac.) = 0.086 Sq. Mi.
Drainage Area for Depth-Area Areal Adjustment = 55.30(Ac.) = 0.086 Sq. Mi.
Length along longest watercourse = 2375.00(Ft.)
Length along longest watercourse measured to centroid = 1715.00(Ft.)
Length along longest watercourse = 0.450 Mi.
Length along longest watercourse measured to centroid = 0.325 Mi.
Difference in elevation = 88.00(Ft.)
Slope along watercourse = 195.6379 Ft./Mi.
Average Manning's 'N' = 0.015
Lag time = 0.064 Hr.
Lag time = 3.82 Min.
25% of lag time = 0.95 Min.
40% of lag time = 1.53 Min.
Unit time = 5.00 Min.
Duration of storm = 24 Hour(s)
User Entered Base Flow = 0.00(CFS)

2 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
55.30	2.50	138.25

100 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
55.30	6.50	359.45

STORM EVENT (YEAR) = 5.00
Area Averaged 2-Year Rainfall = 2.500(In)
Area Averaged 100-Year Rainfall = 6.500(In)

Point rain (area averaged) = 3.437(In)
Areal adjustment factor = 99.99 %
Adjusted average point rain = 3.437(In)

Sub-Area Data:

Area(Ac.)	Runoff Index	Impervious %
55.300	62.60	0.710

Total Area Entered = 55.30(Ac.)

RI AMC2	RI AMC-1	Infil. Rate (In/Hr)	Impervious (Dec.%)	Adj. Infil. Rate (In/Hr)	Area% (Dec.)	F (In/Hr)

62.6 42.6 0.645 0.710 0.233 1.000 0.233
Sum (F) = 0.233

Area averaged mean soil loss (F) (In/Hr) = 0.233
Minimum soil loss rate ((In/Hr)) = 0.116
(for 24 hour storm duration)
Soil low loss rate (decimal) = 0.330

**** RETARDING BASIN ROUTING ****
_____

User entry of depth-outflow-storage data

Total number of inflow hydrograph intervals = 293
Hydrograph time unit = 5.000 (Min.)
Initial depth in storage basin = 0.00(Ft.)

Initial basin depth = 0.00 (Ft.)
Initial basin storage = 0.00 (Ac.Ft)
Initial basin outflow = 0.00 (CFS)

Depth vs. Storage and Depth vs. Discharge data:

Basin Depth (Ft.)	Storage (Ac.Ft)	Outflow (CFS)	(S-O*dt/2) (Ac.Ft)	(S+O*dt/2) (Ac.Ft)

Results of Infiltration Study

August 13, 2021

Exeter Property Group
4602 East University Drive, Suite 185
Phoenix, Arizona 85034

Attention: Mr. Andrew Greybar
Senior Project Manager

Project No.: **21G133-2**

Subject: **Results of Infiltration Testing**
Proposed E-Commerce Development
Cherry Valley Avenue, West of Fabian Lane
Beaumont, California

Reference: Geotechnical Investigation, Proposed E-Commerce Development, Beaumont, California, prepared by Southern California Geotechnical, Inc. (SCG), prepared for Exeter Property Group, SCG Project No. 21G133-1.

Mr. Greybar:

In accordance with your request, we have conducted infiltration testing at the subject site. We are pleased to present this report summarizing the results of the infiltration testing and our design recommendations.

Scope of Services

The scope of services performed for this project was in general accordance with our Change Order No. 21G133-CO, dated July 14, 2021. The scope of services included site reconnaissance, subsurface exploration, field testing, and engineering analysis to determine the infiltration rates of the onsite soils. The infiltration testing was performed in general accordance with the guidelines published in Riverside County – Low Impact Development BMP Design Handbook – Section 2.3 of Appendix A, prepared for the Riverside County Department of Environmental Health (RCDEH), dated December, 2013.

Site and Project Description

The subject site is located on the south side of Cherry Valley Boulevard, 1,500± feet west of the intersection of Cherry Valley Boulevard and Fabian Lane in Beaumont, California. The site is bounded to the north by Cherry Valley Boulevard, to the east by single-family residences (SFRs) and vacant lots, to the south by Brookside Avenue, to the southwest by the Redlands Freeway (Interstate 10) and to the west by vacant land. The general location of the site is illustrated on the Site Location Map, enclosed as Plate 1 in Appendix A of this report.

The overall site consists of several irregular to rectangular-shaped parcels which total 178.4± acres in size. The site is presently developed with three (3) single-family residences and several small abandoned buildings located in the northeastern area of the site. Remnants of shade structures including Portland cement concrete panels and sawed-off poles are present

throughout the northeastern areas of the site. Several above-ground storage tanks are also present throughout the northeastern area of the site. One of the smaller abandoned structures possesses a below-grade room with what appears to be a turbine. The remaining areas of the site are presently vacant and undeveloped. Five (5) circular to oval-shaped leech ponds are located in the west-central area of the site. Two (2) additional leech ponds are located in the south-central area of the site. Ground surface cover consist of exposed soil and moderate to dense native grass and weed growth. Several large trees are located in the southern areas of the site. Limited areas of trash and debris are located throughout the site.

Detailed topographic information was obtained from the conceptual grading plan prepared by Albert A. Webb Associates (Webb). Based on the provided plan, the northeastern to northern two-thirds of the site slopes downward to the southwest at a gradient of 4± percent. The seven (7) circular leech ponds located in the west-central and south-central areas of the site are surrounded by a berm that is 5± feet higher than the surrounding topography. The northwestern area of the site possesses several east-west and southeast-northwest trending drainage courses. The drainage features possess gradual to steep side walls with elevation differences of up to 15± feet below the surrounding topography. To the south of the leech pits, the site slopes towards the south to southwest at a gradient of 10± percent. The topography descends by 50± feet in this area. Another significant east-west trending drainage is located at the base of the descending slope, located in the southern-most region of the site. The drainage possesses gradual to steep side walls with an elevation difference up 10± feet below the surrounding topography. A hill, located to the southeast of this drainage, is approximately 20 to 30 feet higher than the surrounding topography. The hill possesses slope gradients ranging from 14 to 40± percent. To the south of the hill, the site topography slopes gently to the west at a gradient of 3.5± percent, where it meets up with a tributary drainage to the previously mentioned bisecting drainage. The area to the southwest of the bisecting drainage slopes to the west a gradient of 2.5± percent. Another hill with a north-facing descending slope is located at the southwest corner of the site. The slope has a gradient of 20± percent. The maximum site elevation is 2581± feet mean sea level (msl), in the northeast corner of the site. The minimum site elevation is 2406± feet msl, located in drainage swale channel located in the southern-most region of the site.

Proposed Development

Based on the conceptual site plan prepared by Webb, the site will be developed with three (3) new E-Commerce buildings. Building 1 will be 985,860± ft^2 in size, located in the western area of the site. Building 2 will be 1,254,000± ft^2 in size, located in the east-central region of the site. Lastly, Building 3 will be 358,370± ft^2 in size, located in the north-central area of the site. A cross-dock configuration will be constructed on Building 1 and Building 2, along the east/west and north/south building walls, respectively. Dock-high doors will be constructed along a portion of the southern building wall of Building 3. The buildings will be surrounded by asphaltic concrete pavements in the automobile parking and drive areas, Portland cement concrete (PCC) pavements in the truck court, and areas of concrete flatwork and landscape planters. Several new fill and cut slopes will be constructed along all permitters, as well as within the site. The new fill slopes will range from 10 to 40± feet in height and will possess slope inclinations not to exceed 2h:1v (horizontal to vertical). New retaining walls will also be required to establish the

new site grades. The new retaining walls will possess maximum retained heights ranging from 10 to 50± feet.

The proposed development will include on-site stormwater infiltration. Based on our conversations with the project civil engineer and the proposed site plan, infiltration systems will consist of two (2) below-grade chambers and one (1) detention basin. One of the infiltration chamber systems will be located in the northern area of the site (south of Building 3). The bottom of the chambers are expected to range from 28 to 34± feet below the existing site grades. The second infiltration chamber system will be located in the southern area of the site (south of Building 2). The bottom of the chambers are expected to range from 24 to 36± feet below the existing site grades. The detention basin will be located in the south-central area of the site. The bottom of the basin will be at an elevation of, approximately 10 to 43± feet, below the existing site grades.

Concurrent Study

SCG concurrently conducted a geotechnical investigation at the subject site, also referenced above. The investigation conducted for this project consisted of forty-four (44) borings advanced to depths of 10 to 50± feet, and seven (7) trenches excavated to depths of 6½ to 10½± feet below the existing site grades. Artificial fill soils were encountered at the ground surface of several boring and trench locations. The fill soils generally consist of loose to medium dense silty fine sands and clayey fine to medium sands. The fill soils possess a disturbed and mottled appearance, resulting in their classification as artificial fill. Native alluvium was encountered beneath the artificial fill soils or at the ground surface at several of the borings and trench locations. The alluvial soils extend to depths of 2½ to 10± feet below ground surface in the northern areas of the site, and 25 to 50± feet below ground surface in the southern areas of the site. The alluvial soils generally consist of loose to very dense silty fine sands and silty fine to medium sands. Older alluvial soils were encountered at the ground surface, beneath the artificial fill, and/or beneath the alluvium of the boring and trench locations, extending to at least the maximum depth explored of 50± feet below ground surface. The older alluvial soils generally consist of medium dense to very dense silty fine sands, silty fine to medium sands, silty fine to coarse sands and silty fine sands to fine sandy silts.

Groundwater

Groundwater was not encountered at any of the boring or trench locations. Based on the lack of any water within the borings and trenches, and the moisture contents of the recovered soil samples, the static groundwater table is considered to have existed at a depth in excess of 50± feet below existing site grades at the time of the subsurface investigation.

As part of our research, we reviewed available groundwater data in order to determine the historic high groundwater level and recent groundwater level for the site. The primary reference used to determine the groundwater depths in this area is the California Department of Water Resources website, http://www.water.ca.gov/waterdatalibrary/. The nearest monitoring wells in this database are located in the northeast corner of the site. Water level readings within one of these monitoring wells indicates a historic high groundwater level of 317± feet below the ground surface in September 1990. Water level readings within another of these monitoring

wells indicates a recent high groundwater level of 412± feet below the ground surface in December 2020.

Subsurface Exploration

Scope of Exploration

The subsurface exploration conducted for the infiltration testing consisted of sixteen (16) infiltration test borings, advanced to depths ranging from 10 to 43± feet below the existing site grades. The infiltration borings were advanced using a truck-mounted drilling rig, equipped with 8-inch-diameter hollow stem augers and were logged during drilling by a member of our staff. The approximate locations of the infiltration test borings (identified as I-1 through I-16) are indicated on the Infiltration Test Location Plan, enclosed as Plate 2 of this report.

Upon the completion of the infiltration borings, the bottom of each test boring was covered with 2± inches of clean ¾-inch gravel. A sufficient length of 3-inch-diameter perforated PVC casing was then placed into each test hole so that the PVC casing extended from the bottom of the test hole to the ground surface. Clean ¾-inch gravel was then installed in the annulus surrounding the PVC casing.

Geotechnical Conditions

Alluvial soils were encountered at the ground surface some of the infiltration borings, extending to depths of 4 to 32± feet below existing site grades. The alluvial soils in generally consist of loose to dense silty fine sands, silty fine to medium sands, clayey sands, fine to coarse sands, and fine to coarse sandy silts with variable gravel content. Older alluvium was encountered at the ground surface or beneath the alluvium at most of the boring locations. The older alluvium generally consists of medium dense to dense fine sands, fine to coarse sands, silty fine sands, silty fine to medium sands, and clayey fine to medium sands, extending to the maximum depth explored of 43± feet.

Infiltration Testing

As previously mentioned, the infiltration testing was performed in general accordance with the Riverside County guidelines: Riverside County – Low Impact Development BMP Design Handbook – Section 2.3 of Appendix A.

Pre-soaking

In accordance with the county infiltration standards all sixteen (16) of the infiltration test borings were pre-soaked prior to the infiltration testing. The pre-soaking process consisted of filling the test borings by inverting a full 5-gallon bottle of clear water supported over each hole so that the water level reaches a level of at least 5 times the hole's radius above the gravel at the bottom of each hole. The pre-soaking was completed after all of the water had percolated through each test hole or after 15 hours since initiating the pre-soak. Based on the results of the pre-soaking process, different infiltration procedures were used during the infiltration testing at the infiltration boring locations.

Infiltration Testing

Following the pre-soaking process of the infiltration test borings, SCG performed the infiltration testing. Each test hole was filled with water to a depth of at least 5 times the hole's radius above the gravel at the bottom of each test hole, and less than or equal to the water level used during the pre-soaking process. In accordance with the Riverside County guidelines, since "sandy soils" and "non-sandy" conditions were encountered at the bottom of the infiltration borings tests were run for an additional hour with measurements taken at 10-minute intervals for "sandy" conditions and 30-minute intervals for six hours in "non-sandy" conditions. After each reading, the borings were refilled to the correct water level above the gravel at the bottom of each test hole. The water level readings are presented on the spreadsheets enclosed with this report. The infiltration rates for each of the timed intervals are also tabulated on the spreadsheets.

The infiltration rates from the test are tabulated in inches per hour. In accordance with the typically accepted practice, it is recommended that the most conservative reading from the latter part of the infiltration tests be used as the design infiltration rate. The rates are summarized below:

Infiltration Test No.	Depth (feet)	Test Elevation (feet) MSL	Soil Description	Infiltration Rate (inches/hour)
I-1	22	2496	Red Brown fine to coarse Sandy Silt	4.0
I-2	25	2495	Red Brown Silty fine to medium Sand, trace coarse Sand	0.0
I-3	31	2494	Red Brown Clayey fine to coarse Sand, trace Silt	0.0
I-4	34	2496	Red Brown Silty fine to medium Sand, trace coarse Sand	0.0
I-5	24	2474½	Red Brown Silty fine to medium Sand, trace coarse Sand	4.4
I-6	25	2474	Red Brown Silty fine to medium Sand, trace coarse Sand	3.6
I-7	30	2474	Red Brown Silty fine to medium Sand, trace coarse Sand, trace fine Gravel	3.7
I-8	30	2474	Brown Gravelly fine to coarse Sand, little Silt	8.0
I-9	36	2475	Red Brown Silty fine to medium Sand, trace coarse Sand, some fine Gravel	4.2
I-10	35	2475	Brown fine to coarse Sand, trace fine Gravel, trace Silt	8.7
I-11	10	2446	Brown Silty fine to medium Sand, trace fine Gravel	0.8

I-12	14	2443	Red Brown Silty fine to medium Sand, trace coarse Sand, trace fine to coarse Gravel	4.8

Laboratory Testing

Moisture Content

The moisture contents for the recovered soil samples within the borings were determined in accordance with ASTM D-2216 and are expressed as a percentage of the dry weight. These test results are presented on the Boring Logs.

Grain Size Analysis

The grain size distribution of selected soils collected from the bottom of each infiltration test boring have been determined using a range of wire mesh screens. These tests were performed in general accordance with ASTM D-422 and/or ASTM D-1140. The weight of the portion of the sample retained on each screen is recorded and the percentage finer or coarser of the total weight is calculated. The results of these tests are presented on Plates C-1 through C-17 of this report.

Design Recommendations

Sixteen (16) infiltration tests were performed at the subject site. As noted above, the infiltration rates at these locations range from 0 to 19.4 inches per hour.

Based on the results of the infiltration testing, we recommend the following infiltration rates for the proposed infiltration systems:

Infiltration System	Site Location	Infiltration Rate (Inches per Hour)
A	North-Central	0
B	South-Central	5.4
C	South-Central	11.5

We recommend that a representative from the geotechnical engineer be on-site during the construction of the proposed infiltration system to identify the soil classification at the base of the chamber system. It should be confirmed that the soils at the base of the proposed

infiltration system corresponds with those presented in this report to ensure that the performance of the system will be consistent with the rates reported herein.

The design of the proposed storm water infiltration system should be performed by the project civil engineer, in accordance with the City of Beaumont and/or County of Riverside guidelines. However, it is recommended that the system be constructed so as to facilitate removal of silt and clay, or other deleterious materials from any water that may enter the system. The presence of such materials would decrease the effective infiltration rates. **It is recommended that the project civil engineer apply an appropriate factor of safety. The infiltration rate recommended above is based on the assumption that only clean water will be introduced to the subsurface profile. Any fines, debris, or organic materials could significantly impact the infiltration rates.** It should be noted that the recommended infiltration rates are based on infiltration testing at sixteen (16) discrete locations and the overall infiltration rate of the storm water infiltration system could vary considerably.

Infiltration Rate Considerations

The infiltration rates presented herein was determined in accordance with the City of Beaumont and/or County of Riverside guidelines and are considered valid only for the time and place of the actual test. Varying subsurface conditions will exist in other areas of the site, which could alter the recommended infiltration rates presented above. The infiltration rates will decline over time between maintenance cycles as silt or clay particles accumulate on the BMP surface. The infiltration rate is highly dependent upon a number of factors, including density, silt and clay content, grainsize distribution throughout the range of particle sizes, and particle shape. Small changes in these factors can cause large changes in the infiltration rates.

Infiltration rates are based on unsaturated flow. As water is introduced into soils by infiltration, the soils become saturated and the wetting front advances from the unsaturated zone to the saturated zone. Once the soils become saturated, infiltration rates become zero, and water can only move through soils by hydraulic conductivity at a rate determined by pressure head and soil permeability. Changes in soil moisture content will affect the infiltration rate. Infiltration rates should be expected to decrease until the soils become saturated. Soil permeability values will then govern groundwater movement. Permeability values may be on the order of 10 to 20 times less than infiltration rates. The system designer should incorporate adequate factors of safety and allow for overflow design into appropriate traditional storm drain systems, which would transport storm water off-site.

Construction Considerations

The infiltration rates presented in this report are specific to the tested locations and tested depths. Infiltration rates can be significantly reduced if the soils are exposed to excessive disturbance or compaction during construction. Compaction of the soils at the bottom of the infiltration system can significantly reduce the infiltration ability of the basins. Therefore, the subgrade soils within proposed infiltration system areas should not be over-excavated, undercut or compacted in any significant manner. **It is recommended that a note to this effect be added to the project plans and/or specifications.**

We recommend that a representative from the geotechnical engineer be on-site during the construction of the proposed infiltration systems to identify the soil classification at the base of each system. It should be confirmed that the soils at the base of the proposed infiltration systems

correspond with those presented in this report to ensure that the performance of the systems will be consistent with the rates reported herein.

We recommend that scrapers and other rubber-tired heavy equipment not be operated on the basin bottom, or at levels lower than 2 feet above the bottom of the system, particularly within basins. As such, the bottom 24 inches of the infiltration systems should be excavated with non-rubber-tired equipment, such as excavators.

Basin Maintenance

The proposed project may include infiltration basins. Water flowing into these basins will carry some level of sediment. Wind-blown sediments and erosion of the basin side walls will also contribute to sediment deposition at the bottom of the basin. This layer has the potential to significantly reduce the infiltration rate of the basin subgrade soils. Therefore, a formal basin maintenance program should be established to ensure that these silt and clay deposits are removed from the basin on a regular basis. Appropriate vegetation on the basin sidewalls and bottom may reduce erosion and sediment deposition.

Basin maintenance should also include measures to prevent animal burrows, and to repair any burrows or damage caused by such. Animal burrows in the basin sidewalls can significantly increase the risk of erosion and piping failures.

Location of Infiltration Systems

The use of on-site storm water infiltration systems carries a risk of creating adverse geotechnical conditions. Increasing the moisture content of the soil can cause the soil to lose internal shear strength and increase its compressibility, resulting in a change in the designed engineering properties. Overlying structures and pavements in the infiltration area could potentially be damaged due to saturation of the subgrade soils. **The proposed infiltration systems for this site should be located at least 25 feet away from any structures, including retaining walls.** Even with this provision of locating the infiltration system at least 25 feet from the building(s), it is possible that infiltrating water into the subsurface soils could have an adverse effect on the proposed or existing structures. It should also be noted that utility trenches which happen to collect storm water can also serve as conduits to transmit storm water toward the structure, depending on the slope of the utility trench. Therefore, consideration should also be given to the proposed locations of underground utilities which may pass near the proposed infiltration system.

The infiltration system designer should also give special consideration to the effect that the proposed infiltration systems may have on nearby subterranean structures, open excavations, or descending slopes. In particular, infiltration systems should not be located near the crest of descending slopes, particularly where the slopes are comprised of granular soils. Such systems will require specialized design and analysis to evaluate the potential for slope instability, piping failures and other phenomena that typically apply to earthen dam design. This type of analysis is beyond the scope of this infiltration test report, but these factors should be considered by the infiltration system designer when locating the infiltration systems.

General Comments

This report has been prepared as an instrument of service for use by the client in order to aid in the evaluation of this property and to assist the architects and engineers in the design and

preparation of the project plans and specifications. This report may be provided to the contractor(s) and other design consultants to disclose information relative to the project. However, this report is not intended to be utilized as a specification in and of itself, without appropriate interpretation by the project architect, structural engineer, and/or civil engineer. The design of the infiltration system is the responsibility of the civil engineer. The role of the geotechnical engineer is limited to determination of infiltration rate only. By using the design infiltration rates contained herein, the civil engineer agrees to indemnify, defend, and hold harmless the geotechnical engineer for all aspects of the design and performance of the infiltration system. The reproduction and distribution of this report must be authorized by the client and Southern California Geotechnical, Inc. Furthermore, any reliance on this report by an unauthorized third party is at such party's sole risk, and we accept no responsibility for damage or loss which may occur. The analysis of this site was based on a subsurface profile interpolated from limited discrete soil samples. While the materials encountered in the project area are considered to be representative of the total area, some variations should be expected between trench locations and testing depths. If the conditions encountered during construction vary significantly from those detailed herein, we should be contacted immediately to determine if the conditions alter the recommendations contained herein.

This report has been based on assumed or provided characteristics of the proposed development. It is recommended that the owner, client, architect, structural engineer, and civil engineer carefully review these assumptions to ensure that they are consistent with the characteristics of the proposed development. If discrepancies exist, they should be brought to our attention to verify that they do not affect the conclusions and recommendations contained herein. We also recommend that the project plans and specifications be submitted to our office for review to verify that our recommendations have been correctly interpreted. The analysis, conclusions, and recommendations contained within this report have been promulgated in accordance with generally accepted professional geotechnical engineering practice. No other warranty is implied or expressed.

Closure

We sincerely appreciate the opportunity to be of service on this project. We look forward to providing additional consulting services during the course of the project. If we may be of further assistance in any manner, please contact our office.

Respectfully Submitted,

SOUTHERN CALIFORNIA GEOTECHNICAL, INC.

BORING LOG LEGEND

SAMPLE TYPE	GRAPHICAL SYMBOL	SAMPLE DESCRIPTION
AUGER		SAMPLE COLLECTED FROM AUGER CUTTINGS, NO FIELD MEASUREMENT OF SOIL STRENGTH. (DISTURBED)
CORE		ROCK CORE SAMPLE: TYPICALLY TAKEN WITH A DIAMOND-TIPPED CORE BARREL. TYPICALLY USED ONLY IN HIGHLY CONSOLIDATED BEDROCK.
GRAB		SOIL SAMPLE TAKEN WITH NO SPECIALIZED EQUIPMENT, SUCH AS FROM A STOCKPILE OR THE GROUND SURFACE. (DISTURBED)
CS		CALIFORNIA SAMPLER: 2-1/2 INCH I.D. SPLIT BARREL SAMPLER, LINED WITH 1-INCH HIGH BRASS RINGS. DRIVEN WITH SPT HAMMER. (RELATIVELY UNDISTURBED)
NSR		NO RECOVERY: THE SAMPLING ATTEMPT DID NOT RESULT IN RECOVERY OF ANY SIGNIFICANT SOIL OR ROCK MATERIAL.
SPT		STANDARD PENETRATION TEST: SAMPLER IS A 1.4 INCH INSIDE DIAMETER SPLIT BARREL, DRIVEN 18 INCHES WITH THE SPT HAMMER. (DISTURBED)
SH		SHELBY TUBE: TAKEN WITH A THIN WALL SAMPLE TUBE, PUSHED INTO THE SOIL AND THEN EXTRACTED. (UNDISTURBED)
VANE		VANE SHEAR TEST: SOIL STRENGTH OBTAINED USING A 4 BLADED SHEAR DEVICE. TYPICALLY USED IN SOFT CLAYS-NO SAMPLE RECOVERED.

COLUMN DESCRIPTIONS

DEPTH: Distance in feet below the ground surface.

SAMPLE: Sample Type as depicted above.

BLOW COUNT: Number of blows required to advance the sampler 12 inches using a 140 lb hammer with a 30-inch drop. 50/3" indicates penetration refusal (>50 blows) at 3 inches. WH indicates that the weight of the hammer was sufficient to push the sampler 6 inches or more.

POCKET PEN.: Approximate shear strength of a cohesive soil sample as measured by pocket penetrometer.

GRAPHIC LOG: Graphic Soil Symbol as depicted on the following page.

DRY DENSITY: Dry density of an undisturbed or relatively undisturbed sample in lbs/ft^3.

MOISTURE CONTENT: Moisture content of a soil sample, expressed as a percentage of the dry weight.

LIQUID LIMIT: The moisture content above which a soil behaves as a liquid.

PLASTIC LIMIT: The moisture content above which a soil behaves as a plastic.

PASSING #200 SIEVE: The percentage of the sample finer than the #200 standard sieve.

UNCONFINED SHEAR: The shear strength of a cohesive soil sample, as measured in the unconfined state.

INFILTRATION CALCULATIONS

Project Name	Proposed E-Commerce Development
Project Location	Beaumont, CA
Project Number	21G133-2
Engineer	Caleb Brackett

Test Hole Radius	4	(in)
Test Depth	22.00	(ft)

Infiltration Test Hole: I-1

Soil Criteria Test

Interval Number		Time	Time Interval (min)	Water Depth (ft)	Change in Water Level (in)	Did 6 inches of water seep away in less than 25 minutes?	Sandy Soils or Non-Sandy Soils?
1	Initial	11:00 AM	25.00	19.00	23.04	YES	SANDY SOILS
	Final	11:25 AM		20.92			
2	Initial	11:28 AM	25.00	19.00	23.16	YES	SANDY SOILS
	Final	11:53 AM		20.93			

Test Data

Interval Number		Time	Time Interval (min)	Water Depth (ft)	Change in Water Level (ft)	Average Head Height (ft)	Infiltration Rate Q (in/hr)
1	Initial	12:00 PM	10.00	19.00	0.90	2.55	3.98
	Final	12:10 PM		19.90			
2	Initial	12:11 PM	10.00	19.00	0.91	2.55	4.03
	Final	12:21 PM		19.91			
3	Initial	12:22 PM	10.00	19.00	0.90	2.55	3.98
	Final	12:32 PM		19.90			
4	Initial	12:33 PM	10.00	19.00	0.91	2.55	4.03
	Final	12:43 PM		19.91			
5	Initial	12:44 PM	10.00	19.00	0.90	2.55	3.98
	Final	12:54 PM		19.90			
6	Initial	12:55 PM	10.00	19.00	0.90	2.55	3.98
	Final	1:05 PM		19.90			

Per County Standards, Infiltration Rate calculated as follows:

$$Q = \frac{\Delta H(60r)}{\Delta t(r + 2H_{avg})}$$

Where:
- Q = Infiltration Rate (in inches per hour)
- ΔH = Change in Height (Water Level) over the time interval
- r = Test Hole (Borehole) Radius
- Δt = Time Interval
- H_{avg} = Average Head Height over the time interval

6	Initial	11:17 AM	10.00	28.00	0.58	1.71	3.71
	Final	11:27 AM		28.58			

Per County Standards, Infiltration Rate calculated as follows:

$$Q = \frac{\Delta H(60r)}{\Delta t(r + 2H_{avg})}$$

Where:
- Q = Infiltration Rate (in inches per hour)
- ΔH = Change in Height (Water Level) over the time interval
- r = Test Hole (Borehole) Radius
- Δt = Time Interval
- H_{avg} = Average Head Height over the time interval

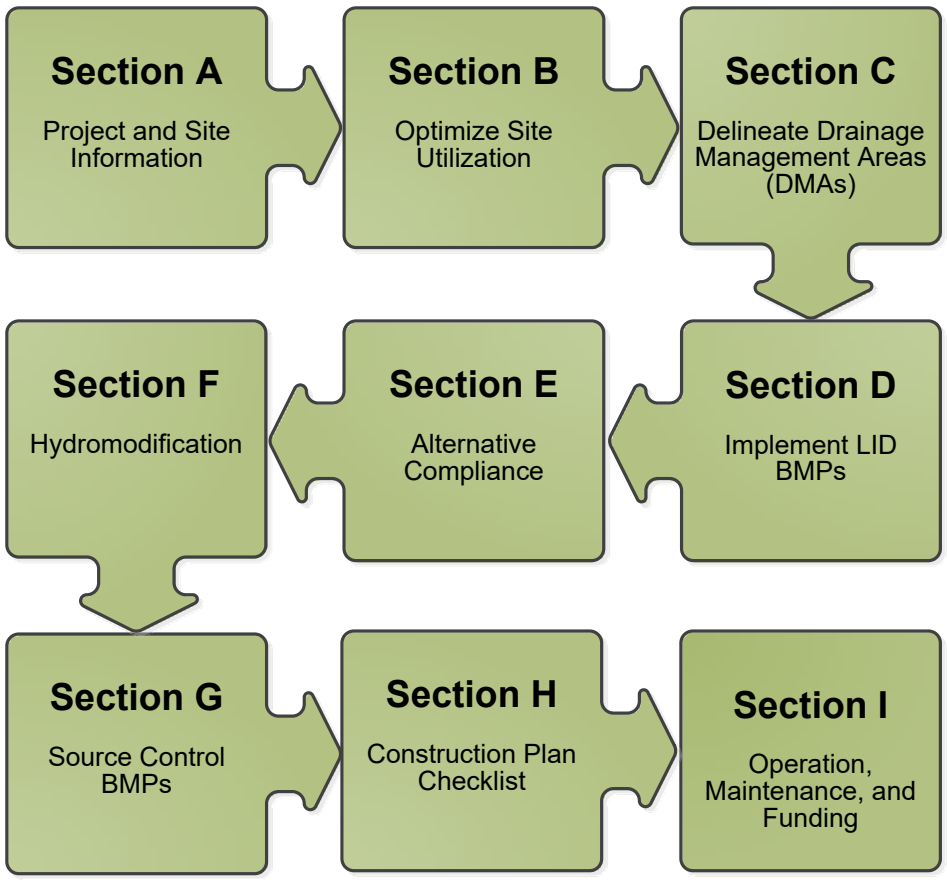
A Brief Introduction

This Project-Specific WQMP Template for the **Santa Ana Region** has been prepared to help guide you in documenting compliance for your project. Because this document has been designed to specifically document compliance, you will need to utilize the WQMP Guidance Document as your "how-to" manual to help guide you through this process. Both the Template and Guidance Document go hand-in-hand, and will help facilitate a well prepared Project-Specific WQMP. Below is a flowchart for the layout of this Template that will provide the steps required to document compliance.



OWNER'S CERTIFICATION

This Project-Specific Water Quality Management Plan (WQMP) has been prepared for Exeter Cherry Valley Land, LLC by Albert A. Webb Associates for the Beaumont Summit Station- Building 1 project.

This WQMP is intended to comply with the requirements of City of Beaumont, County of Riverside for County of Riverside Ordinance No. 754 which includes the requirement for the preparation and implementation of a Project-Specific WQMP.

The undersigned, while owning the property/project described in the preceding paragraph, shall be responsible for the implementation and funding of this WQMP and will ensure that this WQMP is amended as appropriate to reflect up-to-date conditions on the site. In addition, the property owner accepts responsibility for interim operation and maintenance of Stormwater BMPs until such time as this responsibility is formally transferred to a subsequent owner. This WQMP will be reviewed with the facility operator, facility supervisors, employees, tenants, maintenance and service contractors, or any other party (or parties) having responsibility for implementing portions of this WQMP. At least one copy of this WQMP will be maintained at the project site or project office in perpetuity. The undersigned is authorized to certify and to approve implementation of this WQMP. The undersigned is aware that implementation of this WQMP is enforceable under Riverside County Water Quality Ordinance (Municipal Code Section 13.12 – Stormwater Drainage System Protection Regulations).

"I, the undersigned, certify under penalty of law that the provisions of this WQMP have been reviewed and accepted and that the WQMP will be transferred to future successors in interest."

Project Description

The Beaumont Summit Station (BSS)– Building 1 project proposes an e-commerce development in the City of Beaumont on approximately 55.2 acres of mostly vacant land within the boundaries of the 188-acre TPM 38223 (overall BSS project site). The overall BSS project site consists of approximately 188 acres of TPM 38223 which currently contains mostly vacant land with some pavement and structures and is bounded by Cherry Valley Boulevard to the north, Brookside Avenue to the south, residential lots to the east and vacant land to the west. TPM 38223 consists of approximately 145.4 acres of e-commerce, 11.4 acres of commercial, and 31.2 acres of open space areas. The BSS – Building 1 project is bounded by Cherry Valley Boulevard to the north, vacant land to the west, vacant Parcel 5 of TPM 38223 to the south and the future BSS – Building 2 and 3 developments (Design Review No. PW2021-0770 and No. PW2021-0771, respectively) to the east.

The overall project site is currently mostly vacant with some buildings and paved areas in the eastern portion of the site. Runoff from the onsite area currently runs through the site to the southwest. The runoff is conveyed into a natural streambed area that runs along the south and western boundary of the project. This streambed ultimately discharges into a concrete ditch to the northwest of the project site.

For the proposed condition, runoff is captured through a series of inlets located throughout the site at low points. Proposed underground storm drain directs flows towards a proposed underground CMP detention system for increased runoff mitigation. Flows generated by the BSS – Building 1 project development will ultimately discharge to the existing natural streambed to the west of the site.

Based on site grading constraints, an infiltration-based BMP is not feasible. This is due to fill conditions being required for site grading of the BSS – Building 1 area. A bioretention basin is being proposed to treat a portion of the onsite runoff for water quality requirements. Due to site constraints, there is limited adequate landscaped area for the bioretention basin. Therefore, the basin has been sized to treat the Building 1 water quality runoff to the maximum extent practicable. With a bottom area of 5,064 sq. ft. and a minimum infiltration rate, the bioretention will treat approximately 32,410 cubic ft of runoff in the maximum drawdown time of 48 hrs (31.5% of the V_{BMP}). The remaining 70,590 cubic ft of the water quality volume (68.5%) is to be treated by the infiltration basin within the BSS – Building 2 site to the east. The basin has been sized to detain the Building 2 water quality volume and the increased runoff from the site to be mitigated. Since the Building 1 water quality volume is less than the Building 2 water quality volume, the basin will adequately detain the Building 1 volume as it is treated through infiltration. The proposed pump system will be designed in final engineering to ensure that Building 1 water quality flows will not be pumped to the infiltration basin until the Building 2 water quality volume has fully infiltrated. Therefore, the Building 2 CMP chambers were designed to hold the water quality volume as well as the increased runoff volume. As an LID measure, runoff will be pumped to irrigate approximately 20,150 sf of natural vegetation in the southern portion of the project site. Based on a 12-hour irrigation cycle and a minimum infiltration rate of 1.6 in/hr, this LID measure would treat 32,240 cubic ft of runoff per irrigation cycle (approximately 31% of the Building 2 $V_{BMP)}$. This volume was accounted for to be treated by the infiltration basin as a BMP measure.

Some paved access roads and landscaped areas on the northwest region of the site drain offsite to Cherry Valley Boulevard due to grading constraints. The concrete areas have been excluded from this preliminary analysis while the landscaped areas have been considered self-retaining areas.

A.1 Maps and Site Plans

When completing your Project-Specific WQMP, include a map of the local vicinity and existing site. In addition, include all grading, drainage, landscape/plant palette and other pertinent construction plans in Appendix 2. At a **minimum**, your WQMP Site Plan should include the following:

- Drainage Management Areas
- Proposed Structural BMPs
- Drainage Path
- Drainage Infrastructure, Inlets, Overflows
- Source Control BMPs
- Buildings, Roof Lines, Downspouts
- Impervious Surfaces
- Standard Labeling
- BMP Locations (Lat/Long)

Use your discretion on whether or not you may need to create multiple sheets or can appropriately accommodate these features on one or two sheets. Keep in mind that the Co-Permittee plan reviewer must be able to easily analyze your project utilizing this template and its associated site plans and maps.

A.2 Identify Receiving Waters

Using Table A.1 below, list in order of upstream to downstream, the receiving waters that the project site is tributary to. Continue to fill each row with the Receiving Water's 303(d) listed impairments (if any), designated beneficial uses, and proximity, if any, to a RARE beneficial use. Include a map of the receiving waters in Appendix 1.

Table A.1 Identification of Receiving Waters

Receiving Waters	EPA Approved 303(d) List Impairments	Designated Beneficial Uses	Proximity to RARE Beneficial Use
San Timoteo Creek Reach 3 (HUC 801.62)	N/A	GWR, REC1, REC2, WARM, WILD, RARE	N/A
Santa Ana River (Reach 5)	N/A	MUN, AGR, GWR,REC1, REC2, WARM, WILD, RARE	N/A
Santa Ana River (Reach 4)	Pathogens	GWR, REC1, REC2, WARM, WILD, RARE, SPWN	N/A
Santa Ana River (Reach 3)	Copper, Lead, Pathogens	AGR, GWR, REC1, REC2, WARM, WILD, RARE, SPWN	N/A
Prado Basin Management Zone	N/A	REC1, REC2, WARM, WILD, RARE	N/A

A.3 Additional Permits/Approvals required for the Project:

Table A.2 Other Applicable Permits

Agency	Permit Required	
State Department of Fish and Game, 1602 Streambed Alteration Agreement	☐ Y	☒ N
State Water Resources Control Board, Clean Water Act (CWA) Section 401 Water Quality Cert.	☐ Y	☒ N
US Army Corps of Engineers, CWA Section 404 Permit	☐ Y	☒ N
US Fish and Wildlife, Endangered Species Act Section 7 Biological Opinion	☐ Y	☒ N
Statewide Construction General Permit Coverage	☒ Y	☐ N
Statewide Industrial General Permit Coverage	☒ Y	☐ N
Western Riverside MSHCP Consistency Approval (e.g., JPR, DBESP)	☐ Y	☒ N
Other *(please list in the space below as required)* *City of Beaumont Grading Permit*	☒ Y	☐ N

If yes is answered to any of the questions above, the Co-Permittee may require proof of approval/coverage from those agencies as applicable including documentation of any associated requirements that may affect this Project-Specific WQMP.

Section B: Optimize Site Utilization (LID Principles)

Review of the information collected in Section 'A' will aid in identifying the principal constraints on site design and selection of LID BMPs as well as opportunities to reduce imperviousness and incorporate LID Principles into the site and landscape design. For example, **constraints** might include impermeable soils, high groundwater, groundwater pollution or contaminated soils, steep slopes, geotechnical instability, high-intensity land use, heavy pedestrian or vehicular traffic, utility locations or safety concerns. **Opportunities** might include existing natural areas, low areas, oddly configured or otherwise unbuildable parcels, easements and landscape amenities including open space and buffers (which can double as locations for bioretention BMPs), and differences in elevation (which can provide hydraulic head). Prepare a brief narrative for each of the site optimization strategies described below. This narrative will help you as you proceed with your LID design and explain your design decisions to others.

The 2010 Santa Ana MS4 Permit further requires that LID Retention BMPs (Infiltration Only or Harvest and Use) be used unless it can be shown that those BMPs are infeasible. Therefore, it is important that your narrative identify and justify if there are any constraints that would prevent the use of those categories of LID BMPs. Similarly, you should also note opportunities that exist which will be utilized during project design. Upon completion of identifying Constraints and Opportunities, include these on your WQMP Site plan in Appendix 1.

Consideration of "highest and best use" of the discharge should also be considered. For example, Lake Elsinore is evaporating faster than runoff from natural precipitation can recharge it. Requiring infiltration of 85% of runoff events for projects tributary to Lake Elsinore would only exacerbate current water quality problems associated with Pollutant concentration due to lake water evaporation. In cases where rainfall events have low potential to recharge Lake Elsinore (i.e. no hydraulic connection between groundwater to Lake Elsinore, or other factors), requiring infiltration of Urban Runoff from projects is counterproductive to the overall watershed goals. Project proponents, in these cases, would be allowed to discharge Urban Runoff, provided they used equally effective filtration-based BMPs.

Site Optimization

The following questions are based upon Section 3.2 of the WQMP Guidance Document. Review of the WQMP Guidance Document will help you determine how best to optimize your site and subsequently identify opportunities and/or constraints, and document compliance.

Did you identify and preserve existing drainage patterns? If so, how? If not, why?

The current site generally drains from northeast to southwest towards an existing natural streambed. In this existing condition, runoff generally sheet flows towards the streambed which runs northwest along the southwestern project boundary. In the developed condition, a network of inlets will capture flows generated onsite. Flows are conveyed towards a proposed CMP detention system for increased runoff mitigation. From the detention system, the water quality volume is pumped to various basins for treatment. All onsite flows ultimately discharge into the existing streambed area to the west of the project site, preserving the existing drainage pattern.

Did you identify and protect existing vegetation? If so, how? If not, why?

The existing project site has minimal vegetation, so no vegetation is proposed to be protected.

Did you identify and preserve natural infiltration capacity? If so, how? If not, why?

The proposed site is in fill condition, therefore it is not feasible to preserve natural infiltration capacity within the Building 1 site. A portion of the water quality volume is proposed to be treated by infiltration within the Building 2 infiltration basin, which has a recommended infiltration rate of 11.5 in/hr based on a geotechnical investigation.

Did you identify and minimize impervious area? If so, how? If not, why?

The impervious areas will be minimized as much as possible while maintaining safe and usable facilities onsite. Landscaped areas have been provided throughout the projects site along concrete walkways, around the proposed building, adjacent to parking areas, and in other feasible locations throughout the site.

Did you identify and disperse runoff to adjacent pervious areas? If so, how? If not, why?

Yes, however, based on the nature of the e-commerce development, not all runoff can feasibly be directed towards a pervious area before being captured. Pervious landscaped areas are proposed throughout the site where possible in order to maximize the chances of runoff dispersing into landscaped areas before being captured. As an LID measure, a portion of the water quality volume will be pumped to irrigate natural vegetation along the southern project boundary. Runoff that is captured onsite will be directed towards a CMP detention system to be pumped to a bioretention basin or an infiltration basin for treatment.

Section C: Delineate Drainage Management Areas (DMAs)

Utilizing the procedure in Section 3.3 of the WQMP Guidance Document which discusses the methods of delineating and mapping your project site into individual DMAs, complete Table C.1 below to appropriately categorize the types of classification (e.g., Type A, Type B, etc.) per DMA for your project site. Upon completion of this table, this information will then be used to populate and tabulate the corresponding tables for their respective DMA classifications.

Table C.1 DMA Classifications

DMA Name or ID	Surface Type(s)[1][2]	Area (Sq. Ft.)	DMA Type
DMA 1 - Concrete	Concrete or Asphalt	750,724	D
DMA 1- L/S	Ornamental Landscaping	119,487	D
DMA 1- Roofs	Roofs	985,860	D
DMA 1- Basin	Ornamental Landscaping	5,060	D

[1]Reference Table 2-1 in the WQMP Guidance Document to populate this column
[2]If multi-surface provide back-up

Table C.2 Type 'A', Self-Treating Areas

DMA Name or ID	**Area (Sq. Ft.)**	**Stabilization Type**	**Irrigation Type (if any)**
DMA 1	390,655	Grasses/shrubs	Reclaimed water

Table C.3 Type 'B', Self-Retaining Areas

Self-Retaining Area				**Type 'C' DMAs that are draining to the Self-Retaining Area**		
DMA Name/ ID	Post-project surface type	Area (square feet) [A]	Storm Depth (inches) [B]	DMA Name / ID	[C] from Table C.4 = [C]	Required Retention Depth (inches) [D]

$$[D] = [B] + \frac{[B] \cdot [C]}{[A]}$$

Table C.4 Type 'C', Areas that Drain to Self-Retaining Areas

DMA					Receiving Self-Retaining DMA		
DMA Name/ ID	Area (square feet) [A]	Post-project surface type	Impervious fraction [B]	Product [C] = [A] x [B]	DMA name /ID	Area (square feet) [D]	Ratio [C]/[D]

Table C.5 Type 'D', Areas Draining to BMPs

DMA Name or ID	BMP Name or ID
DMA 1	Bioretention Basin

Note: More than one drainage management area can drain to a single LID BMP, however, one drainage management area may not drain to more than one BMP.

Section D: Implement LID BMPs

D.1 Infiltration Applicability

Is there an approved downstream 'Highest and Best Use' for stormwater runoff (see discussion in Chapter 2.4.4 of the WQMP Guidance Document for further details)? ☐ Y ☒ N

If yes has been checked, Infiltration BMPs shall not be used for the site; proceed to section D.3
If no, continue working through this section to implement your LID BMPs. It is recommended that you contact your Co-Permittee to verify whether or not your project discharges to an approved downstream 'Highest and Best Use' feature.

Geotechnical Report

A Geotechnical Report or Phase I Environmental Site Assessment may be required by the Copermittee to confirm present and past site characteristics that may affect the use of Infiltration BMPs. In addition, the Co-Permittee, at their discretion, may not require a geotechnical report for small projects as described in Chapter 2 of the WQMP Guidance Document. If a geotechnical report has been prepared, include it in Appendix 3. In addition, if a Phase I Environmental Site Assessment has been prepared, include it in Appendix 4.
Is this project classified as a small project consistent with the requirements of Chapter 2 of the WQMP Guidance Document? ☐ Y ☒ N

Infiltration Feasibility

Table D.1 below is meant to provide a simple means of assessing which DMAs on your site support Infiltration BMPs and is discussed in the WQMP Guidance Document in Chapter 2.4.5. Check the appropriate box for each question and then list affected DMAs as applicable. If additional space is needed, add a row below the corresponding answer.

Table D.1 Infiltration Feasibility

Does the project site…	YES	NO
…have any DMAs with a seasonal high groundwater mark shallower than 10 feet?		X
If Yes, list affected DMAs:		
…have any DMAs located within 100 feet of a water supply well?		X
If Yes, list affected DMAs:		
…have any areas identified by the geotechnical report as posing a public safety risk where infiltration of stormwater could have a negative impact?		X
If Yes, list affected DMAs:		
…have measured in-situ infiltration rates of less than 1.6 inches / hour?		X
If Yes, list affected DMAs:		
…have significant cut and/or fill conditions that would preclude in-situ testing of infiltration rates at the final infiltration surface?	X*	
If Yes, list affected DMAs: DMA 1		
…geotechnical report identify other site-specific factors that would preclude effective and safe infiltration?		X
Describe here:		

If you answered "Yes" to any of the questions above for any DMA, Infiltration BMPs should not be used for those DMAs and you should proceed to the assessment for Harvest and Use below.
**Due to the fill conditions throughout the BSS – Building 1 site, infiltration was not feasible within the project site and therefore the proposed underground chambers for increased runoff mitigation will not be perforated. A bioretention basin is proposed to treat the water quality flows to the maximum extent practicable due to the sizing constraints within the Building 1 site. The remainder of the flows are proposed to be pumped to the BSS – Builiding 2 infiltration basin for treatment. Based on a geotechnical report, the proposed infiltration basin area has a recommended infiltration rate of 11.5 in/hr.*

D.2 Harvest and Use Assessment

Please check what applies*:*

☒ Reclaimed water will be used for the non-potable water demands for the project.

☐ Downstream water rights may be impacted by Harvest and Use as approved by the Regional Board (verify with the Copermittee).

☐ The Design Capture Volume will be addressed using Infiltration Only BMPs. In such a case, Harvest and Use BMPs are still encouraged, but it would not be required if the Design Capture Volume will be infiltrated or evapotranspired.

If any of the above boxes have been checked, Harvest and Use BMPs need not be assessed for the site. If none of the above criteria applies, follow the steps below to assess the feasibility of irrigation use, toilet use and other non-potable uses (e.g., industrial use).

Irrigation Use Feasibility

Complete the following steps to determine the feasibility of harvesting stormwater runoff for Irrigation Use BMPs on your site:

Step 1: Identify the total area of irrigated landscape on the site, and the type of landscaping used.

Total Area of Irrigated Landscape: N/A

Type of Landscaping (Conservation Design or Active Turf): N/A

Step 2: Identify the planned total of all impervious areas on the proposed project from which runoff might be feasibly captured and stored for irrigation use. Depending on the configuration of buildings and other impervious areas on the site, you may consider the site as a whole, or parts of the site, to evaluate reasonable scenarios for capturing and storing runoff and directing the stored runoff to the potential use(s) identified in Step 1 above.

Total Area of Impervious Surfaces: N/A

Step 3: Cross reference the Design Storm depth for the project site (see Exhibit A of the WQMP Guidance Document) with the left column of Table 2-3 in Chapter 2 to determine the minimum area of Effective Irrigated Area per Tributary Impervious Area (EIATIA).

Enter your EIATIA factor: N/A

Step 4: Multiply the unit value obtained from Step 3 by the total of impervious areas from Step 2 to develop the minimum irrigated area that would be required.

Minimum required irrigated area: N/A

Step 5: Determine if harvesting stormwater runoff for irrigation use is feasible for the project by comparing the total area of irrigated landscape (Step 1) to the minimum required irrigated area (Step 4).

Minimum required irrigated area (Step 4)	Available Irrigated Landscape (Step 1)
N/A	N/A

Toilet Use Feasibility

Complete the following steps to determine the feasibility of harvesting stormwater runoff for toilet flushing uses on your site:

Step 1: Identify the projected total number of daily toilet users during the wet season, and account for any periodic shut downs or other lapses in occupancy:

Projected Number of Daily Toilet Users: N/A

Project Type: N/A

Step 2: Identify the planned total of all impervious areas on the proposed project from which runoff might be feasibly captured and stored for toilet use. Depending on the configuration of buildings and other impervious areas on the site, you may consider the site as a whole, or parts of the site, to evaluate reasonable scenarios for capturing and storing runoff and directing the stored runoff to the potential use(s) identified in Step 1 above.

Total Area of Impervious Surfaces: N/A

Step 3: Enter the Design Storm depth for the project site (see Exhibit A) into the left column of Table 2-2 in Chapter 2 to determine the minimum number or toilet users per tributary impervious acre (TUTIA).

Enter your TUTIA factor: N/A

Step 4: Multiply the unit value obtained from Step 3 by the total of impervious areas from Step 2 to develop the minimum number of toilet users that would be required.

Minimum number of toilet users: N/A

Step 5: Determine if harvesting stormwater runoff for toilet flushing use is feasible for the project by comparing the Number of Daily Toilet Users (Step 1) to the minimum required number of toilet users (Step 4).

Minimum required Toilet Users (Step 4)	**Projected number of toilet users (Step 1)**
N/A	N/A

Other Non-Potable Use Feasibility

Are there other non-potable uses for stormwater runoff on the site (e.g. industrial use)? See Chapter 2 of the Guidance for further information. If yes, describe below. If no, write N/A.

N/A

Step 1: Identify the projected average daily non-potable demand, in gallons per day, during the wet season and accounting for any periodic shut downs or other lapses in occupancy or operation.

Average Daily Demand: N/A

Step 2: Identify the planned total of all impervious areas on the proposed project from which runoff might be feasibly captured and stored for the identified non-potable use. Depending on the configuration of buildings and other impervious areas on the site, you may consider the site as a whole, or parts of the site, to evaluate reasonable scenarios for capturing and storing runoff and directing the stored runoff to the potential use(s) identified in Step 1 above.

Total Area of Impervious Surfaces: N/A

Step 3: Enter the Design Storm depth for the project site (see Exhibit A) into the left column of Table 2-4 in Chapter 2 to determine the minimum demand for non-potable uses per tributary impervious acre.

Enter the factor from Table 2-4: N/A

Step 4: Multiply the unit value obtained from Step 3 by the total of impervious areas from Step 2 to develop the minimum number of gallons per day of non-potable use that would be required.

Minimum required use: N/A

Step 5: Determine if harvesting stormwater runoff for other non-potable use is feasible for the project by comparing the projected average daily use (Step 1) to the minimum required non-potable use (Step 4).

Minimum required non-potable use (Step 4)	**Projected average daily use (Step 1)**
N/A	N/A

If Irrigation, Toilet and Other Use feasibility anticipated demands are less than the applicable minimum values, Harvest and Use BMPs are not required and you should proceed to utilize LID Bioretention and Biotreatment per Section 3.4.2 of the WQMP Guidance Document.

Harvest and Use is proposed as an LID measure only for a portion of the runoff. Approximately 32,240 cf of runoff will be pumped to irrigate the natural vegetation along the southern boundary of the site. This volume was accounted for in the analysis of the 70,590 cf of runoff to be pumped to the BSS – Building 2 infiltration basin for treatment as a BMP measure.

D.3 Bioretention and Biotreatment Assessment

Other LID Bioretention and Biotreatment BMPs as described in Chapter 2.4.7 of the WQMP Guidance Document are feasible on nearly all development sites with sufficient advance planning.

Select one of the following:

☒ LID Bioretention/Biotreatment BMPs will be used for some or all DMAs of the project as noted below in Section D.4 (note the requirements of Section 3.4.2 in the WQMP Guidance Document).

☐ A site-specific analysis demonstrating the technical infeasibility of all LID BMPs has been performed and is included in Appendix 5. If you plan to submit an analysis demonstrating the technical infeasibility of LID BMPs, request a pre-submittal meeting with the Copermittee to discuss this option. Proceed to Section E to document your alternative compliance measures.

D.4 Feasibility Assessment Summaries

From the Infiltration, Harvest and Use, Bioretention and Biotreatment Sections above, complete Table D.2 below to summarize which LID BMPs are technically feasible, and which are not, based upon the established hierarchy.

Table D.2 LID Prioritization Summary Matrix

DMA Name/ID	LID BMP Hierarchy				No LID (Alternative Compliance)
	1. Infiltration	2. Harvest and use	3. Bioretention	4. Biotreatment	
DMA 1-A	☐	☐	☐	☒*	☐
	☐	☐	☐	☐	☐
	☐	☐	☐	☐	☐
	☐	☐	☐	☐	☐

For those DMAs where LID BMPs are not feasible, provide a brief narrative below summarizing why they are not feasible, include your technical infeasibility criteria in Appendix 5, and proceed to Section E below to document Alternative Compliance measures for those DMAs. Recall that each proposed DMA must pass through the LID BMP hierarchy before alternative compliance measures may be considered.

**Based on the LID BMP Hierarchy, the BSS – Building 1 project will utilize bioretention to treat for water quality requirements. Onsite infiltration-based BMPs are not feasible due to fill conditions throughout the Building 1 site. Harvest and use BMPs are not feasible as reclaimed water will be used for non-potable water demands. Bioretention BMPs will be proposed to treat for water quality to the maximum extent possible. All water quality flows in excess of the bioretention basin capacity will be pumped to be treated by the infiltration basin within the Building 2 site to the east.*

D.5 LID BMP Sizing

Each LID BMP must be designed to ensure that the Design Capture Volume will be addressed by the selected BMPs. First**,** calculate the Design Capture Volume for each LID BMP using the V_{BMP} worksheet in Appendix F of the LID BMP Design Handbook. Second**,** design the LID BMP to meet the required V_{BMP} using a method approved by the Copermittee. Utilize the worksheets found in the LID BMP Design Handbook or consult with your Copermittee to assist you in correctly sizing your LID BMPs. Complete Table D.3 below to document the Design Capture Volume and the Proposed Volume for each LID BMP. Provide the completed design procedure sheets for each LID BMP in Appendix 6. You may add additional rows to the table below as needed.

Table D.3 DCV Calculations for LID BMPs

DMA Type/ID	DMA Area (square feet)	Post-Project Surface Type	Effective Impervious Fraction, I_f	DMA Runoff Factor	DMA Areas x Runoff Factor	*DMA 1*		
	[A]		[B]	[C]	[A] x [C]			
Roof	*985,860*	*Roofs*	*1*	*0.89*	*879,387.1*			
Concrete/Asphalt	*750,724*	*Concrete/Asphalt*	*1*	*0.89*	*669,645.8*			
Landscaping	*119,487*	*Ornamental Landscaping*	*0.1*	*0.11*	*13,198.3*			
Basin	*5,060*	*Ornamental Landscaping*	*0.1*	*0.11*	*558.9*	*Design Storm Depth (in)*	*Design Capture Value,* $\mathbf{V_{BMP}}$ *(cubic feet)*	*Proposed Volume on Plans (cubic feet)*
	$A_T = \Sigma[A]$ **1,861,131**				Σ= [D] **1,562,790.1**	[E] **0.79**	$[F] = \frac{[D]x[E]}{12}$ **102,883.7**	[G] **103,000**

[B], [C] is obtained as described in Section 2.3.1 of the WQMP Guidance Document

[E] is obtained from Exhibit A in the WQMP Guidance Document

[G] is obtained from a design procedure sheet, such as in LID BMP Design Handbook and placed in Appendix 6

Section E: Alternative Compliance (LID Waiver Program)

LID BMPs are expected to be feasible on virtually all projects. Where LID BMPs have been demonstrated to be infeasible as documented in Section D, other Treatment Control BMPs must be used (subject to LID waiver approval by the Copermittee). Check one of the following Boxes:

☒ LID Principles and LID BMPs have been incorporated into the site design to fully address all Drainage Management Areas. No alternative compliance measures are required for this project and thus this Section is not required to be completed.

- *Or* -

☐ The following Drainage Management Areas are unable to be addressed using LID BMPs. A site-specific analysis demonstrating technical infeasibility of LID BMPs has been approved by the Co-Permittee and included in Appendix 5. Additionally, no downstream regional and/or sub-regional LID BMPs exist or are available for use by the project. The following alternative compliance measures on the following pages are being implemented to ensure that any pollutant loads expected to be discharged by not incorporating LID BMPs, are fully mitigated.

N/A

E.1 Identify Pollutants of Concern

Utilizing Table A.1 from Section A above which noted your project's receiving waters and their associated EPA approved 303(d) listed impairments, cross reference this information with that of your selected Priority Development Project Category in Table E.1 below. If the identified General Pollutant Categories are the same as those listed for your receiving waters, then these will be your Pollutants of Concern and the appropriate box or boxes will be checked on the last row. The purpose of this is to document compliance and to help you appropriately plan for mitigating your Pollutants of Concern in lieu of implementing LID BMPs.

Table E.1 Potential Pollutants by Land Use Type

Priority Development Project Categories and/or Project Features (check those that apply)	General Pollutant Categories							
	Bacterial Indicators	Metals	Nutrients	Pesticides	Toxic Organic Compounds	Sediments	Trash & Debris	Oil & Grease
☐ Detached Residential Development	P	N	P	P	N	P	P	P
☐ Attached Residential Development	P	N	P	P	N	P	P	P[(2)]
☒ Commercial/Industrial Development	P[(3)]	P	P[(1)]	P[(1)]	P[(5)]	P[(1)]	P	P
☐ Automotive Repair Shops	N	P	N	N	P[(4, 5)]	N	P	P
☐ Restaurants (>5,000 ft^2)	P	N	N	N	N	N	P	P
☐ Hillside Development (>5,000 ft^2)	P	N	P	P	N	P	P	P
☐ Parking Lots (>5,000 ft^2)	P[(6)]	P	P[(1)]	P[(1)]	P[(4)]	P[(1)]	P	P
☐ Retail Gasoline Outlets	N	P	N	N	P	N	P	P
Project Priority Pollutant(s) of Concern	☒	☒	☒	☒	☒	☒	☒	☒

P = Potential

N = Not Potential

(1) A potential Pollutant if non-native landscaping exists or is proposed onsite; otherwise not expected

(2) A potential Pollutant if the project includes uncovered parking areas; otherwise not expected

(3) A potential Pollutant is land use involving animal waste

(4) Specifically petroleum hydrocarbons

(5) Specifically solvents

(6) Bacterial indicators are routinely detected in pavement runoff

E.2 Stormwater Credits

Projects that cannot implement LID BMPs but nevertheless implement smart growth principles are potentially eligible for Stormwater Credits. Utilize Table 3-8 within the WQMP Guidance Document to identify your Project Category and its associated Water Quality Credit. If not applicable, write N/A.

Table E.2 Water Quality Credits

Qualifying Project Categories	Credit Percentage[2]
N/A	N/A
Total Credit Percentage[1]	

[1]*Cannot Exceed 50%*

[2]*Obtain corresponding data from Table 3-8 in the WQMP Guidance Document*

E.3 Sizing Criteria

After you appropriately considered Stormwater Credits for your project, utilize Table E.3 below to appropriately size them to the DCV, or Design Flow Rate, as applicable. Please reference Chapter 3.5.2 of the WQMP Guidance Document for further information.

Table E.3 Treatment Control BMP Sizing

DMA Type/ID	**DMA Area (square feet)**	**Post-Project Surface Type**	**Effective Impervious Fraction, I_f**	**DMA Runoff Factor**	**DMA Area x Runoff Factor**		***Enter BMP Name / Identifier Here***		
	[A]		[B]	[C]	[A] x [C]				
N/A						*Design Storm Depth (in)*	*Minimum Design Capture Volume or Design Flow Rate (cubic feet or cfs)*	*Total Storm Water Credit % Reduction*	*Proposed Volume or Flow on Plans (cubic feet or cfs)*
	A_T = Σ[A]				Σ= [D]	[E]	$[F] = \frac{[D]x[E]}{[G]}$	[F] X (1-[H])	[I]

[B], [C] is obtained as described in Section 2.3.1 from the WQMP Guidance Document

[E] is for Flow-Based Treatment Control BMPs [E] = .2, for Volume-Based Control Treatment BMPs, [E] obtained from Exhibit A in the WQMP Guidance Document

[G] is for Flow-Based Treatment Control BMPs [G] = 43,560, for Volume-Based Control Treatment BMPs, [G] = 12

[H] is from the Total Credit Percentage as Calculated from Table E.2 above

[I] as obtained from a design procedure sheet from the BMP manufacturer and should be included in Appendix 6

E.4 Treatment Control BMP Selection

Treatment Control BMPs typically provide proprietary treatment mechanisms to treat potential pollutants in runoff, but do not sustain significant biological processes. Treatment Control BMPs must have a removal efficiency of a medium or high effectiveness as quantified below:

- **High**: equal to or greater than 80% removal efficiency
- **Medium**: between 40% and 80% removal efficiency

Such removal efficiency documentation (e.g., studies, reports, etc.) as further discussed in Chapter 3.5.2 of the WQMP Guidance Document, must be included in Appendix 6. In addition, ensure that proposed Treatment Control BMPs are properly identified on the WQMP Site Plan in Appendix 1.

Table E.4 Treatment Control BMP Selection

Selected Treatment Control BMP Name or ID[1]	Priority Pollutant(s) of Concern to Mitigate[2]	Removal Efficiency Percentage[3]

[1] Treatment Control BMPs must not be constructed within Receiving Waters. In addition, a proposed Treatment Control BMP may be listed more than once if they possess more than one qualifying pollutant removal efficiency.

[2] Cross Reference Table E.1 above to populate this column.

[3] As documented in a Co-Permittee Approved Study and provided in Appendix 6.

Section F: Hydromodification

F.1 Hydrologic Conditions of Concern (HCOC) Analysis

Once you have determined that the LID design is adequate to address water quality requirements, you will need to assess if the proposed LID Design may still create a HCOC. Review Chapters 2 and 3 (including Figure 3-7) of the WQMP Guidance Document to determine if your project must mitigate for Hydromodification impacts. If your project meets one of the following criteria which will be indicated by the check boxes below, you do not need to address Hydromodification at this time. However, if the project does not qualify for Exemptions 1, 2 or 3, then additional measures must be added to the design to comply with HCOC criteria. This is discussed in further detail below in Section F.2.

HCOC EXEMPTION 1: The Priority Development Project disturbs less than one acre. The Copermittee has the discretion to require a Project-Specific WQMP to address HCOCs on projects less than one acre on a case by case basis. The disturbed area calculation should include all disturbances associated with larger common plans of development.

Does the project qualify for this HCOC Exemption? ☐ Y ☒ N

If Yes, HCOC criteria do not apply.

HCOC EXEMPTION 2: The volume and time of concentration[1] of storm water runoff for the post-development condition is not significantly different from the pre-development condition for a 2-year return frequency storm (a difference of 5% or less is considered insignificant) using one of the following methods to calculate:

- Riverside County Hydrology Manual
- Technical Release 55 (TR-55): Urban Hydrology for Small Watersheds (NRCS 1986), or derivatives thereof, such as the Santa Barbara Urban Hydrograph Method
- Other methods acceptable to the Co-Permittee

Does the project qualify for this HCOC Exemption? ☐ Y ☒ N

If Yes, report results in Table F.1 below and provide your substantiated hydrologic analysis in Appendix 7.

Table F.1 Hydrologic Conditions of Concern Summary

	2 year – 24 hour		
	Pre-condition	**Post-condition**	**% Difference**
Time of Concentration	N/A	N/A	N/A
Volume (Cubic Feet)	N/A	N/A	N/A

[1] Time of concentration is defined as the time after the beginning of the rainfall when all portions of the drainage basin are contributing to flow at the outlet.

HCOC EXEMPTION 3: All downstream conveyance channels to an adequate sump (for example, Prado Dam, Lake Elsinore, Canyon Lake, Santa Ana River, or other lake, reservoir or naturally erosion resistant feature) that will receive runoff from the project are engineered and regularly maintained to ensure design flow capacity; no sensitive stream habitat areas will be adversely affected; or are not identified on the Co-Permittees Hydromodification Susceptibility Maps.

Does the project qualify for this HCOC Exemption? ☐ Y ☒ N

If Yes, HCOC criteria do not apply and note below which adequate sump applies to this HCOC qualifier:

F.2 HCOC Mitigation

If none of the above HCOC Exemption Criteria are applicable, HCOC criteria is considered mitigated if they meet one of the following conditions:

a. Additional LID BMPS are implemented onsite or offsite to mitigate potential erosion or habitat impacts as a result of HCOCs. This can be conducted by an evaluation of site-specific conditions utilizing accepted professional methodologies published by entities such as the California Stormwater Quality Association (CASQA), the Southern California Coastal Water Research Project (SCCRWP), or other Co-Permittee approved methodologies for site-specific HCOC analysis.

b. The project is developed consistent with an approved Watershed Action Plan that addresses HCOC in Receiving Waters.

c. Mimicking the pre-development hydrograph with the post-development hydrograph, for a 2-year return frequency storm. Generally, the hydrologic conditions of concern are not significant, if the post-development hydrograph is no more than 10% greater than pre-development hydrograph. In cases where excess volume cannot be infiltrated or captured and reused, discharge from the site must be limited to a flow rate no greater than 110% of the pre-development 2-year peak flow.

Be sure to include all pertinent documentation used in your analysis of the items a, b or c in Appendix 7.

The site does not meet the HCOC exemption criteria listed in Section F.1, therefore the site has been designed to mitigate the proposed flows to be no more than 10% of the pre-development 2-year peak flow rate generated by the BSS – Building 1 site, as allowed by option C listed above. Unit hydrograph and routing analyses were performed for the 2-year storm event. A CMP chamber detention system is proposed along with an orifice outlet to mitigate the proposed condition flows. In the existing condition, approximately 106.4 acres were analyzed as Area A and include the BSS – Building 1 site. In the proposed condition, approximately 55.3 acres of Area A are referred to as the West Area and correspond to the BSS - Building 1 site. The unit hydrograph results show that Area A generates a 24-hour, 2-year peak flow of 4.33 cfs. The proposed condition analyses resulted in the West Area generating a 24-hour, 2-year peak flow of 12.7 cfs. The West Area accounts for approximately 83.4% of Area A, therefore the proposed condition flow generated by the West Area was routed to be within 10% of 3.6 cfs, which is 83.4% of the existing condition peak flow of Area A. A CMP chamber system sized to detain 300,000 cf of runoff and a 4-inch orifice were proposed for the routing and resulted in a peak flow of 3.3 cfs for the West Area (BSS-Building 1) site. Each of the Beaumont Summit Station building sites were analyzed along with the overall site to ensure that while some building sites are over mitigating or under mitigating due to the breakdown of the site based on grading constraints, overall the project will be fully mitigated once developed. The results for the 2-year storm event of BSS – Building 1 have been included in Appendix 7 and detailed information regarding the analyses can be found in the "Beaumont Summit Station – Building 1 Preliminary Drainage Study".

	EXISTING CONDITION 2-YEAR, 24-HOUR STORM		
		VOL (AC-FT)	PEAK FLOW (CFS)
	AREA A	2.7	4.3
X	83.4% AREA A (PROP. WEST AREA)	-	3.6
	16.6% AREA A (PROP. NORTH AREA)	-	0.7
	AREA B (PROP. SOUTH AREA)	3.9	6.4

	PROPOSED CONDITION 2-YEAR, 24-HOUR STORM			
		VOL (AC-FT)	PEAK FLOW (CFS)	ROUTING PEAK FLOW (CFS)
X	WEST AREA	7.7	12.7	3.3
	NORTH AREA	5.0	8.2	0.7
	EX. AREA A COMBINED	12.7	20.9	4.0
	SOUTH AREA (EX. AREA B)	9.7	16.0	0*

**South Area is tributary to a proposed infiltration basin with a factored infiltration rate of 9.4 cfs. The South Area 2-yr, 24-hour runoff is fully infiltrated by the basin at the factored rate. The effective runoff leaving the South Area tributary is 0 cfs.*

*Note: **X** signals area for Building-1. Matching colors from existing and proposed conditions are the same site outlet; the contributory tributaries are different and can span multiple building areas.*

*The entire site is shown for continuity, but only those areas with **X** will have Unit Hydrograph and Routing output included in Appendix 7.*

Section G: Source Control BMPs

Source control BMPs include permanent, structural features that may be required in your project plans — such as roofs over and berms around trash and recycling areas — and Operational BMPs, such as regular sweeping and "housekeeping", that must be implemented by the site's occupant or user. The MEP standard typically requires both types of BMPs. In general, Operational BMPs cannot be substituted for a feasible and effective permanent BMP. Using the Pollutant Sources/Source Control Checklist in Appendix 8, review the following procedure to specify Source Control BMPs for your site:

1. ***Identify Pollutant Sources*:** Review Column 1 in the Pollutant Sources/Source Control Checklist. Check off the potential sources of Pollutants that apply to your site.

2. ***Note Locations on Project-Specific WQMP Exhibit*:** Note the corresponding requirements listed in Column 2 of the Pollutant Sources/Source Control Checklist. Show the location of each Pollutant source and each permanent Source Control BMP in your Project-Specific WQMP Exhibit located in Appendix 1.

3. ***Prepare a Table and Narrative*:** Check off the corresponding requirements listed in Column 3 in the Pollutant Sources/Source Control Checklist. In the left column of Table G.1 below, list each potential source of runoff Pollutants on your site (from those that you checked in the Pollutant Sources/Source Control Checklist). In the middle column, list the corresponding permanent, Structural Source Control BMPs (from Columns 2 and 3 of the Pollutant Sources/Source Control Checklist) used to prevent Pollutants from entering runoff. **Add additional narrative** in this column that explains any special features, materials or methods of construction that will be used to implement these permanent, Structural Source Control BMPs.

4. ***Identify Operational Source Control BMPs:*** To complete your table, refer once again to the Pollutant Sources/Source Control Checklist. List in the right column of your table the Operational BMPs that should be implemented as long as the anticipated activities continue at the site. Copermittee stormwater ordinances require that applicable Source Control BMPs be implemented; the same BMPs may also be required as a condition of a use permit or other revocable Discretionary Approval for use of the site.

Table G.1 Permanent and Operational Source Control Measures

Potential Sources of Runoff pollutants	Permanent Structural Source Control BMPs	Operational Source Control BMPs
On-site storm drain inlets	*Mark all inlets with the words "Only Rain Down the Storm Drain" or similar. Catch Basin Markers may be available from the Riverside County Flood Control and Water Conservation District, call 951.955.1200 to verify.*	*Maintain and periodically repaint or replace inlet markings.* *Provide stormwater pollution prevention information to new site owners, lessees, or operators.* *See applicable operational BMPs in Fact Sheet SC-44, "Drainage System Maintenance," in the CASQA Stormwater Quality Handbooks at www.cabmphandbooks.com*

Interior floor drains and elevator shaft sump	*The interior floor drains and elevator shaft sump pumps will be plumbed to sanitary sewer*	*Inspect and maintain drains to prevent blockages and overflow.*
Landscape/Outdoor Pesticide Use	*Preserve existing native trees, shrubs, and ground cover to the maximum extent possible.* *Design landscaping to minimize irrigation and runoff, to promote surface infiltration where appropriate, and to minimize the use of fertilizers and pesticides that can contribute to stormwater pollution.* *Where landscaped areas are used to retain or detain stormwater, specify plants that are tolerant of saturated soil conditions.* *Consider using pest-resistant plants, especially adjacent to hardscape.* *To ensure successful establishment, select plants appropriate to site soils, slopes, climate, sun, wind, rain, land use, air movement, ecological consistency, and plant interactions.*	*Maintain landscaping using minimum or no pesticides.* *See applicable operational BMPs in "What you should know for…..Landscape and Gardening" at http://rcflood.org/stormwater/* *Provide IPM information to new owners, lessees and operators.* *Sweep plazas, sidewalks, and parking lots regularly to prevent accumulation of litter and debris. Collect debris from pressure washing to prevent entry into the storm drain system. Collect washwater containing any cleaning agent or degreaser and discharge to the sanitary sewer not to a storm drain.*
Refuse Areas	*Trash container storage areas shall be paved with an impervious surface, designed not to allow run-on from adjoining areas, designed to divert drainage from adjoining roofs and pavements from the surrounding area, and screened or walled to prevent off-site transport of trash.* *Trash dumpsters (containers) shall be leak proof and have attached covers or lids.* *Trash enclosures shall be roofed per City standards.* *Trash compactors shall be roofed and set on a concrete pad per City standards. The pad shall be a minimum of one foot larger all around than the trash compactor and sloped to drain to a sanitary sewer line. Connection of trash area drains to the MS4 is prohibited.* *See CASQA SD-32 BMP Fact Sheets in Appendix 10 for additional information.*	*Adequate number of receptacles shall be provided. Inspect receptacles regularly; repair or replace leaky receptacles. Keep receptacles covered. Prohibit/prevent dumping of liquid or hazardous wastes. Post "no hazardous materials" signs. Inspect and pick up litter daily and clean up spills immediately. Keep spill control materials available on-site. See Fact Sheet SC-34, in Appendix 10, "Waste Handling and Disposal" in the CASQA Stormwater Quality Handbook at www.cabmphandbooks.com*

	Signs shall be posted on or near dumpsters with the words "Do not dump hazardous materials here" or similar.	
Plazas, Sidewalks and parking lots.		*Sweep plazas, sidewalks, and parking lots regularly to prevent accumulation of litter and debris. Collect debris from pressure washing to prevent entry into the storm drain system. Collect washwater containing any cleaning agent or degreaser and discharge to the sanitary sewer not to a storm drain.*
Loading Docks	*Show a preliminary design for the loading dock area, including roofing and drainage. Loading docks shall be covered and/or graded to minimize run-on to and runoff from the loading area. Roof downspouts shall be positioned to direct stormwater away from the loading area. Water from loading dock areas shall be drained to the sanitary sewer, or diverted and collected for ultimate discharge to the sanitary sewer.* *Loading dock areas draining directly to the sanitary sewer shall be equipped with a spill control valve or equivalent device, which shall be kept closed during periods of operation.* *Provide a roof overhang over the loading area or install door skirts (cowling) at each bay that enclose the end of the trailer.*	*Move loaded and unloaded items indoors as soon as possible.* *See Fact Sheet SC-30, "Outdoor Loading and Unloading," in the CASQA Stormwater Quality Handbooks at www.cabmphandbooks.com*
Fire Sprinkler Test Water	*Water discharged from the fire sprinkler systems shall not enter the storm drain system. Discharged water from fire sprinkler testing shall be collected and used for onsite landscape or disposed of at a local waste water treatment plant.*	*See the note in Fact Sheet SC-41, "Building and Grounds Maintenance," in the CASQA Stormwater Quality Handbooks at www.cabmphandbooks.com*

Section H: Construction Plan Checklist

Populate Table H.1 below to assist the plan checker in an expeditious review of your project. The first two columns will contain information that was prepared in previous steps, while the last column will be populated with the corresponding plan sheets. This table is to be completed with the submittal of your final Project-Specific WQMP.

Table H.1 Construction Plan Cross-reference

BMP No. or ID	BMP Identifier and Description	Corresponding Plan Sheet(s)	BMP Location (Lat/Long)
DMA 1	Bioretention Basin	Appendix 6	

Note that the updated table — or Construction Plan WQMP Checklist — is **only a reference tool** to facilitate an easy comparison of the construction plans to your Project-Specific WQMP. Co-Permittee staff can advise you regarding the process required to propose changes to the approved Project-Specific WQMP.

Section H will be completed and addressed during Final WQMP.

Section I: Operation, Maintenance and Funding

The Copermittee will periodically verify that Stormwater BMPs on your site are maintained and continue to operate as designed. To make this possible, your Copermittee will require that you include in Appendix 9 of this Project-Specific WQMP:

1. A means to finance and implement facility maintenance in perpetuity, including replacement cost.
2. Acceptance of responsibility for maintenance from the time the BMPs are constructed until responsibility for operation and maintenance is legally transferred. A warranty covering a period following construction may also be required.
3. An outline of general maintenance requirements for the Stormwater BMPs you have selected.
4. Figures delineating and designating pervious and impervious areas, location, and type of Stormwater BMP, and tables of pervious and impervious areas served by each facility. Geo-locating the BMPs using a coordinate system of latitude and longitude is recommended to help facilitate a future statewide database system.
5. A separate list and location of self-retaining areas or areas addressed by LID Principles that do not require specialized O&M or inspections but will require typical landscape maintenance as noted in Chapter 5, pages 85-86, in the WQMP Guidance. Include a brief description of typical landscape maintenance for these areas.

Your local Co-Permittee will also require that you prepare and submit a detailed Stormwater BMP Operation and Maintenance Plan that sets forth a maintenance schedule for each of the Stormwater BMPs built on your site. An agreement assigning responsibility for maintenance and providing for inspections and certification may also be required.

Details of these requirements and instructions for preparing a Stormwater BMP Operation and Maintenance Plan are in Chapter 5 of the WQMP Guidance Document.

Maintenance Mechanism: WQMP Covenant and Agreement

Will the proposed BMPs be maintained by a Home Owners' Association (HOA) or Property Owners Association (POA)?

☒ Y ☐ N

Include your Operation and Maintenance Plan and Maintenance Mechanism in Appendix 9. Additionally, include all pertinent forms of educational materials for those personnel that will be maintaining the proposed BMPs within this Project-Specific WQMP in Appendix 10.

Geotechnical Study and Other Infiltration Testing Data

August 13, 2021

Exeter Property Group
4602 East University Drive, Suite 185
Phoenix, Arizona 85034

Attention: Mr. Andrew Greybar
Senior Project Manager

Project No.: **21G133-2**

Subject: **Results of Infiltration Testing**
Proposed E-Commerce Development
Cherry Valley Avenue, West of Fabian Lane
Beaumont, California

Reference: Geotechnical Investigation, Proposed E-Commerce Development, Beaumont, California, prepared by Southern California Geotechnical, Inc. (SCG), prepared for Exeter Property Group, SCG Project No. 21G133-1.

Mr. Greybar:

In accordance with your request, we have conducted infiltration testing at the subject site. We are pleased to present this report summarizing the results of the infiltration testing and our design recommendations.

Scope of Services

The scope of services performed for this project was in general accordance with our Change Order No. 21G133-CO, dated July 14, 2021. The scope of services included site reconnaissance, subsurface exploration, field testing, and engineering analysis to determine the infiltration rates of the onsite soils. The infiltration testing was performed in general accordance with the guidelines published in Riverside County – Low Impact Development BMP Design Handbook – Section 2.3 of Appendix A, prepared for the Riverside County Department of Environmental Health (RCDEH), dated December, 2013.

Site and Project Description

The subject site is located on the south side of Cherry Valley Boulevard, 1,500± feet west of the intersection of Cherry Valley Boulevard and Fabian Lane in Beaumont, California. The site is bounded to the north by Cherry Valley Boulevard, to the east by single-family residences (SFRs) and vacant lots, to the south by Brookside Avenue, to the southwest by the Redlands Freeway (Interstate 10) and to the west by vacant land. The general location of the site is illustrated on the Site Location Map, enclosed as Plate 1 in Appendix A of this report.

The overall site consists of several irregular to rectangular-shaped parcels which total 178.4± acres in size. The site is presently developed with three (3) single-family residences and several small abandoned buildings located in the northeastern area of the site. Remnants of shade structures including Portland cement concrete panels and sawed-off poles are present

throughout the northeastern areas of the site. Several above-ground storage tanks are also present throughout the northeastern area of the site. One of the smaller abandoned structures possesses a below-grade room with what appears to be a turbine. The remaining areas of the site are presently vacant and undeveloped. Five (5) circular to oval-shaped leech ponds are located in the west-central area of the site. Two (2) additional leech ponds are located in the south-central area of the site. Ground surface cover consist of exposed soil and moderate to dense native grass and weed growth. Several large trees are located in the southern areas of the site. Limited areas of trash and debris are located throughout the site.

Detailed topographic information was obtained from the conceptual grading plan prepared by Albert A. Webb Associates (Webb). Based on the provided plan, the northeastern to northern two-thirds of the site slopes downward to the southwest at a gradient of 4± percent. The seven (7) circular leech ponds located in the west-central and south-central areas of the site are surrounded by a berm that is 5± feet higher than the surrounding topography. The northwestern area of the site possesses several east-west and southeast-northwest trending drainage courses. The drainage features possess gradual to steep side walls with elevation differences of up to 15± feet below the surrounding topography. To the south of the leech pits, the site slopes towards the south to southwest at a gradient of 10± percent. The topography descends by 50± feet in this area. Another significant east-west trending drainage is located at the base of the descending slope, located in the southern-most region of the site. The drainage possesses gradual to steep side walls with an elevation difference up 10± feet below the surrounding topography. A hill, located to the southeast of this drainage, is approximately 20 to 30 feet higher than the surrounding topography. The hill possesses slope gradients ranging from 14 to 40± percent. To the south of the hill, the site topography slopes gently to the west at a gradient of 3.5± percent, where it meets up with a tributary drainage to the previously mentioned bisecting drainage. The area to the southwest of the bisecting drainage slopes to the west a gradient of 2.5± percent. Another hill with a north-facing descending slope is located at the southwest corner of the site. The slope has a gradient of 20± percent. The maximum site elevation is 2581± feet mean sea level (msl), in the northeast corner of the site. The minimum site elevation is 2406± feet msl, located in drainage swale channel located in the southern-most region of the site.

Proposed Development

Based on the conceptual site plan prepared by Webb, the site will be developed with three (3) new E-Commerce buildings. Building 1 will be 985,860± ft^2 in size, located in the western area of the site. Building 2 will be 1,254,000± ft^2 in size, located in the east-central region of the site. Lastly, Building 3 will be 358,370± ft^2 in size, located in the north-central area of the site. A cross-dock configuration will be constructed on Building 1 and Building 2, along the east/west and north/south building walls, respectively. Dock-high doors will be constructed along a portion of the southern building wall of Building 3. The buildings will be surrounded by asphaltic concrete pavements in the automobile parking and drive areas, Portland cement concrete (PCC) pavements in the truck court, and areas of concrete flatwork and landscape planters. Several new fill and cut slopes will be constructed along all permitters, as well as within the site. The new fill slopes will range from 10 to 40± feet in height and will possess slope inclinations not to exceed 2h:1v (horizontal to vertical). New retaining walls will also be required to establish the

new site grades. The new retaining walls will possess maximum retained heights ranging from 10 to 50± feet.

The proposed development will include on-site stormwater infiltration. Based on our conversations with the project civil engineer and the proposed site plan, infiltration systems will consist of two (2) below-grade chambers and one (1) detention basin. One of the infiltration chamber systems will be located in the northern area of the site (south of Building 3). The bottom of the chambers are expected to range from 28 to 34± feet below the existing site grades. The second infiltration chamber system will be located in the southern area of the site (south of Building 2). The bottom of the chambers are expected to range from 24 to 36± feet below the existing site grades. The detention basin will be located in the south-central area of the site. The bottom of the basin will be at an elevation of, approximately 10 to 43± feet, below the existing site grades.

Concurrent Study

SCG concurrently conducted a geotechnical investigation at the subject site, also referenced above. The investigation conducted for this project consisted of forty-four (44) borings advanced to depths of 10 to 50± feet, and seven (7) trenches excavated to depths of 6½ to 10½± feet below the existing site grades. Artificial fill soils were encountered at the ground surface of several boring and trench locations. The fill soils generally consist of loose to medium dense silty fine sands and clayey fine to medium sands. The fill soils possess a disturbed and mottled appearance, resulting in their classification as artificial fill. Native alluvium was encountered beneath the artificial fill soils or at the ground surface at several of the borings and trench locations. The alluvial soils extend to depths of 2½ to 10± feet below ground surface in the northern areas of the site, and 25 to 50± feet below ground surface in the southern areas of the site. The alluvial soils generally consist of loose to very dense silty fine sands and silty fine to medium sands. Older alluvial soils were encountered at the ground surface, beneath the artificial fill, and/or beneath the alluvium of the boring and trench locations, extending to at least the maximum depth explored of 50± feet below ground surface. The older alluvial soils generally consist of medium dense to very dense silty fine sands, silty fine to medium sands, silty fine to coarse sands and silty fine sands to fine sandy silts.

Groundwater

Groundwater was not encountered at any of the boring or trench locations. Based on the lack of any water within the borings and trenches, and the moisture contents of the recovered soil samples, the static groundwater table is considered to have existed at a depth in excess of 50± feet below existing site grades at the time of the subsurface investigation.

As part of our research, we reviewed available groundwater data in order to determine the historic high groundwater level and recent groundwater level for the site. The primary reference used to determine the groundwater depths in this area is the California Department of Water Resources website, http://www.water.ca.gov/waterdatalibrary/. The nearest monitoring wells in this database are located in the northeast corner of the site. Water level readings within one of these monitoring wells indicates a historic high groundwater level of 317± feet below the ground surface in September 1990. Water level readings within another of these monitoring

wells indicates a recent high groundwater level of 412± feet below the ground surface in December 2020.

Subsurface Exploration

Scope of Exploration

The subsurface exploration conducted for the infiltration testing consisted of sixteen (16) infiltration test borings, advanced to depths ranging from 10 to 43± feet below the existing site grades. The infiltration borings were advanced using a truck-mounted drilling rig, equipped with 8-inch-diameter hollow stem augers and were logged during drilling by a member of our staff. The approximate locations of the infiltration test borings (identified as I-1 through I-16) are indicated on the Infiltration Test Location Plan, enclosed as Plate 2 of this report.

Upon the completion of the infiltration borings, the bottom of each test boring was covered with 2± inches of clean ¾-inch gravel. A sufficient length of 3-inch-diameter perforated PVC casing was then placed into each test hole so that the PVC casing extended from the bottom of the test hole to the ground surface. Clean ¾-inch gravel was then installed in the annulus surrounding the PVC casing.

Geotechnical Conditions

Alluvial soils were encountered at the ground surface some of the infiltration borings, extending to depths of 4 to 32± feet below existing site grades. The alluvial soils in generally consist of loose to dense silty fine sands, silty fine to medium sands, clayey sands, fine to coarse sands, and fine to coarse sandy silts with variable gravel content. Older alluvium was encountered at the ground surface or beneath the alluvium at most of the boring locations. The older alluvium generally consists of medium dense to dense fine sands, fine to coarse sands, silty fine sands, silty fine to medium sands, and clayey fine to medium sands, extending to the maximum depth explored of 43± feet.

Infiltration Testing

As previously mentioned, the infiltration testing was performed in general accordance with the Riverside County guidelines: Riverside County – Low Impact Development BMP Design Handbook – Section 2.3 of Appendix A.

Pre-soaking

In accordance with the county infiltration standards all sixteen (16) of the infiltration test borings were pre-soaked prior to the infiltration testing. The pre-soaking process consisted of filling the test borings by inverting a full 5-gallon bottle of clear water supported over each hole so that the water level reaches a level of at least 5 times the hole's radius above the gravel at the bottom of each hole. The pre-soaking was completed after all of the water had percolated through each test hole or after 15 hours since initiating the pre-soak. Based on the results of the pre-soaking process, different infiltration procedures were used during the infiltration testing at the infiltration boring locations.

Infiltration Testing

Following the pre-soaking process of the infiltration test borings, SCG performed the infiltration testing. Each test hole was filled with water to a depth of at least 5 times the hole's radius above the gravel at the bottom of each test hole, and less than or equal to the water level used during the pre-soaking process. In accordance with the Riverside County guidelines, since "sandy soils" and "non-sandy" conditions were encountered at the bottom of the infiltration borings tests were run for an additional hour with measurements taken at 10-minute intervals for "sandy" conditions and 30-minute intervals for six hours in "non-sandy" conditions. After each reading, the borings were refilled to the correct water level above the gravel at the bottom of each test hole. The water level readings are presented on the spreadsheets enclosed with this report. The infiltration rates for each of the timed intervals are also tabulated on the spreadsheets.

The infiltration rates from the test are tabulated in inches per hour. In accordance with the typically accepted practice, it is recommended that the most conservative reading from the latter part of the infiltration tests be used as the design infiltration rate. The rates are summarized below:

Infiltration Test No.	Depth (feet)	Test Elevation (feet) MSL	Soil Description	Infiltration Rate (inches/hour)
I-1	22	2496	Red Brown fine to coarse Sandy Silt	4.0
I-2	25	2495	Red Brown Silty fine to medium Sand, trace coarse Sand	0.0
I-3	31	2494	Red Brown Clayey fine to coarse Sand, trace Silt	0.0
I-4	34	2496	Red Brown Silty fine to medium Sand, trace coarse Sand	0.0
I-5	24	2474½	Red Brown Silty fine to medium Sand, trace coarse Sand	4.4
I-6	25	2474	Red Brown Silty fine to medium Sand, trace coarse Sand	3.6
I-7	30	2474	Red Brown Silty fine to medium Sand, trace coarse Sand, trace fine Gravel	3.7
I-8	30	2474	Brown Gravelly fine to coarse Sand, little Silt	8.0
I-9	36	2475	Red Brown Silty fine to medium Sand, trace coarse Sand, some fine Gravel	4.2
I-10	35	2475	Brown fine to coarse Sand, trace fine Gravel, trace Silt	8.7
I-11	10	2446	Brown Silty fine to medium Sand, trace fine Gravel	0.8

I-12	14	2443	Red Brown Silty fine to medium Sand, trace coarse Sand, trace fine to coarse Gravel	4.8
I-13	28	2445	Brown fine to coarse Sand, little fine Gravel, little Silt	19.4
I-14	16	2444	Gray Brown Gravelly fine to coarse Sand, little Silt	13.5
I-15	27	2449	Red Brown Silty fine to coarse Sand, trace fine Gravel	15.7
I-16	43	2445	Red Brown Silty fine to medium Sand, trace coarse Sand	14.6

Laboratory Testing

Moisture Content

The moisture contents for the recovered soil samples within the borings were determined in accordance with ASTM D-2216 and are expressed as a percentage of the dry weight. These test results are presented on the Boring Logs.

Grain Size Analysis

The grain size distribution of selected soils collected from the bottom of each infiltration test boring have been determined using a range of wire mesh screens. These tests were performed in general accordance with ASTM D-422 and/or ASTM D-1140. The weight of the portion of the sample retained on each screen is recorded and the percentage finer or coarser of the total weight is calculated. The results of these tests are presented on Plates C-1 through C-17 of this report.

Design Recommendations

Sixteen (16) infiltration tests were performed at the subject site. As noted above, the infiltration rates at these locations range from 0 to 19.4 inches per hour.

Based on the results of the infiltration testing, we recommend the following infiltration rates for the proposed infiltration systems:

Infiltration System	Site Location	Infiltration Rate (Inches per Hour)
A	North-Central	0
B	South-Central	5.4
C	South-Central	11.5

We recommend that a representative from the geotechnical engineer be on-site during the construction of the proposed infiltration system to identify the soil classification at the base of the chamber system. It should be confirmed that the soils at the base of the proposed

infiltration system corresponds with those presented in this report to ensure that the performance of the system will be consistent with the rates reported herein.

The design of the proposed storm water infiltration system should be performed by the project civil engineer, in accordance with the City of Beaumont and/or County of Riverside guidelines. However, it is recommended that the system be constructed so as to facilitate removal of silt and clay, or other deleterious materials from any water that may enter the system. The presence of such materials would decrease the effective infiltration rates. **It is recommended that the project civil engineer apply an appropriate factor of safety. The infiltration rate recommended above is based on the assumption that only clean water will be introduced to the subsurface profile. Any fines, debris, or organic materials could significantly impact the infiltration rates.** It should be noted that the recommended infiltration rates are based on infiltration testing at sixteen (16) discrete locations and the overall infiltration rate of the storm water infiltration system could vary considerably.

Infiltration Rate Considerations

The infiltration rates presented herein was determined in accordance with the City of Beaumont and/or County of Riverside guidelines and are considered valid only for the time and place of the actual test. Varying subsurface conditions will exist in other areas of the site, which could alter the recommended infiltration rates presented above. The infiltration rates will decline over time between maintenance cycles as silt or clay particles accumulate on the BMP surface. The infiltration rate is highly dependent upon a number of factors, including density, silt and clay content, grainsize distribution throughout the range of particle sizes, and particle shape. Small changes in these factors can cause large changes in the infiltration rates.

Infiltration rates are based on unsaturated flow. As water is introduced into soils by infiltration, the soils become saturated and the wetting front advances from the unsaturated zone to the saturated zone. Once the soils become saturated, infiltration rates become zero, and water can only move through soils by hydraulic conductivity at a rate determined by pressure head and soil permeability. Changes in soil moisture content will affect the infiltration rate. Infiltration rates should be expected to decrease until the soils become saturated. Soil permeability values will then govern groundwater movement. Permeability values may be on the order of 10 to 20 times less than infiltration rates. The system designer should incorporate adequate factors of safety and allow for overflow design into appropriate traditional storm drain systems, which would transport storm water off-site.

Construction Considerations

The infiltration rates presented in this report are specific to the tested locations and tested depths. Infiltration rates can be significantly reduced if the soils are exposed to excessive disturbance or compaction during construction. Compaction of the soils at the bottom of the infiltration system can significantly reduce the infiltration ability of the basins. Therefore, the subgrade soils within proposed infiltration system areas should not be over-excavated, undercut or compacted in any significant manner. **It is recommended that a note to this effect be added to the project plans and/or specifications.**

We recommend that a representative from the geotechnical engineer be on-site during the construction of the proposed infiltration systems to identify the soil classification at the base of each system. It should be confirmed that the soils at the base of the proposed infiltration systems

correspond with those presented in this report to ensure that the performance of the systems will be consistent with the rates reported herein.

We recommend that scrapers and other rubber-tired heavy equipment not be operated on the basin bottom, or at levels lower than 2 feet above the bottom of the system, particularly within basins. As such, the bottom 24 inches of the infiltration systems should be excavated with non-rubber-tired equipment, such as excavators.

Basin Maintenance

The proposed project may include infiltration basins. Water flowing into these basins will carry some level of sediment. Wind-blown sediments and erosion of the basin side walls will also contribute to sediment deposition at the bottom of the basin. This layer has the potential to significantly reduce the infiltration rate of the basin subgrade soils. Therefore, a formal basin maintenance program should be established to ensure that these silt and clay deposits are removed from the basin on a regular basis. Appropriate vegetation on the basin sidewalls and bottom may reduce erosion and sediment deposition.

Basin maintenance should also include measures to prevent animal burrows, and to repair any burrows or damage caused by such. Animal burrows in the basin sidewalls can significantly increase the risk of erosion and piping failures.

Location of Infiltration Systems

The use of on-site storm water infiltration systems carries a risk of creating adverse geotechnical conditions. Increasing the moisture content of the soil can cause the soil to lose internal shear strength and increase its compressibility, resulting in a change in the designed engineering properties. Overlying structures and pavements in the infiltration area could potentially be damaged due to saturation of the subgrade soils. **The proposed infiltration systems for this site should be located at least 25 feet away from any structures, including retaining walls.** Even with this provision of locating the infiltration system at least 25 feet from the building(s), it is possible that infiltrating water into the subsurface soils could have an adverse effect on the proposed or existing structures. It should also be noted that utility trenches which happen to collect storm water can also serve as conduits to transmit storm water toward the structure, depending on the slope of the utility trench. Therefore, consideration should also be given to the proposed locations of underground utilities which may pass near the proposed infiltration system.

The infiltration system designer should also give special consideration to the effect that the proposed infiltration systems may have on nearby subterranean structures, open excavations, or descending slopes. In particular, infiltration systems should not be located near the crest of descending slopes, particularly where the slopes are comprised of granular soils. Such systems will require specialized design and analysis to evaluate the potential for slope instability, piping failures and other phenomena that typically apply to earthen dam design. This type of analysis is beyond the scope of this infiltration test report, but these factors should be considered by the infiltration system designer when locating the infiltration systems.

General Comments

This report has been prepared as an instrument of service for use by the client in order to aid in the evaluation of this property and to assist the architects and engineers in the design and

preparation of the project plans and specifications. This report may be provided to the contractor(s) and other design consultants to disclose information relative to the project. However, this report is not intended to be utilized as a specification in and of itself, without appropriate interpretation by the project architect, structural engineer, and/or civil engineer. The design of the infiltration system is the responsibility of the civil engineer. The role of the geotechnical engineer is limited to determination of infiltration rate only. By using the design infiltration rates contained herein, the civil engineer agrees to indemnify, defend, and hold harmless the geotechnical engineer for all aspects of the design and performance of the infiltration system. The reproduction and distribution of this report must be authorized by the client and Southern California Geotechnical, Inc. Furthermore, any reliance on this report by an unauthorized third party is at such party's sole risk, and we accept no responsibility for damage or loss which may occur. The analysis of this site was based on a subsurface profile interpolated from limited discrete soil samples. While the materials encountered in the project area are considered to be representative of the total area, some variations should be expected between trench locations and testing depths. If the conditions encountered during construction vary significantly from those detailed herein, we should be contacted immediately to determine if the conditions alter the recommendations contained herein.

This report has been based on assumed or provided characteristics of the proposed development. It is recommended that the owner, client, architect, structural engineer, and civil engineer carefully review these assumptions to ensure that they are consistent with the characteristics of the proposed development. If discrepancies exist, they should be brought to our attention to verify that they do not affect the conclusions and recommendations contained herein. We also recommend that the project plans and specifications be submitted to our office for review to verify that our recommendations have been correctly interpreted. The analysis, conclusions, and recommendations contained within this report have been promulgated in accordance with generally accepted professional geotechnical engineering practice. No other warranty is implied or expressed.

Closure

We sincerely appreciate the opportunity to be of service on this project. We look forward to providing additional consulting services during the course of the project. If we may be of further assistance in any manner, please contact our office.

Respectfully Submitted,

BORING LOG LEGEND

SAMPLE TYPE	GRAPHICAL SYMBOL	SAMPLE DESCRIPTION
AUGER		SAMPLE COLLECTED FROM AUGER CUTTINGS, NO FIELD MEASUREMENT OF SOIL STRENGTH. (DISTURBED)
CORE		ROCK CORE SAMPLE: TYPICALLY TAKEN WITH A DIAMOND-TIPPED CORE BARREL. TYPICALLY USED ONLY IN HIGHLY CONSOLIDATED BEDROCK.
GRAB		SOIL SAMPLE TAKEN WITH NO SPECIALIZED EQUIPMENT, SUCH AS FROM A STOCKPILE OR THE GROUND SURFACE. (DISTURBED)
CS		CALIFORNIA SAMPLER: 2-1/2 INCH I.D. SPLIT BARREL SAMPLER, LINED WITH 1-INCH HIGH BRASS RINGS. DRIVEN WITH SPT HAMMER. (RELATIVELY UNDISTURBED)
NSR		NO RECOVERY: THE SAMPLING ATTEMPT DID NOT RESULT IN RECOVERY OF ANY SIGNIFICANT SOIL OR ROCK MATERIAL.
SPT		STANDARD PENETRATION TEST: SAMPLER IS A 1.4 INCH INSIDE DIAMETER SPLIT BARREL, DRIVEN 18 INCHES WITH THE SPT HAMMER. (DISTURBED)
SH		SHELBY TUBE: TAKEN WITH A THIN WALL SAMPLE TUBE, PUSHED INTO THE SOIL AND THEN EXTRACTED. (UNDISTURBED)
VANE		VANE SHEAR TEST: SOIL STRENGTH OBTAINED USING A 4 BLADED SHEAR DEVICE. TYPICALLY USED IN SOFT CLAYS-NO SAMPLE RECOVERED.

COLUMN DESCRIPTIONS

DEPTH: Distance in feet below the ground surface.

SAMPLE: Sample Type as depicted above.

BLOW COUNT: Number of blows required to advance the sampler 12 inches using a 140 lb hammer with a 30-inch drop. 50/3" indicates penetration refusal (>50 blows) at 3 inches. WH indicates that the weight of the hammer was sufficient to push the sampler 6 inches or more.

POCKET PEN.: Approximate shear strength of a cohesive soil sample as measured by pocket penetrometer.

GRAPHIC LOG: Graphic Soil Symbol as depicted on the following page.

DRY DENSITY: Dry density of an undisturbed or relatively undisturbed sample in lbs/ft^3.

MOISTURE CONTENT: Moisture content of a soil sample, expressed as a percentage of the dry weight.

LIQUID LIMIT: The moisture content above which a soil behaves as a liquid.

PLASTIC LIMIT: The moisture content above which a soil behaves as a plastic.

PASSING #200 SIEVE: The percentage of the sample finer than the #200 standard sieve.

UNCONFINED SHEAR: The shear strength of a cohesive soil sample, as measured in the unconfined state.

INFILTRATION CALCULATIONS

Project Name	Proposed E-Commerce Development
Project Location	Beaumont, CA
Project Number	21G133-2
Engineer	Caleb Brackett

Test Hole Radius	4	(in)
Test Depth	22.00	(ft)

Infiltration Test Hole: I-1

Soil Criteria Test

Interval Number		Time	Time Interval (min)	Water Depth (ft)	Change in Water Level (in)	Did 6 inches of water seep away in less than 25 minutes?	Sandy Soils or Non-Sandy Soils?
1	Initial	11:00 AM	25.00	19.00	23.04	YES	SANDY SOILS
	Final	11:25 AM		20.92			
2	Initial	11:28 AM	25.00	19.00	23.16	YES	SANDY SOILS
	Final	11:53 AM		20.93			

Test Data

Interval Number		Time	Time Interval (min)	Water Depth (ft)	Change in Water Level (ft)	Average Head Height (ft)	Infiltration Rate Q (in/hr)
1	Initial	12:00 PM	10.00	19.00	0.90	2.55	3.98
	Final	12:10 PM		19.90			
2	Initial	12:11 PM	10.00	19.00	0.91	2.55	4.03
	Final	12:21 PM		19.91			
3	Initial	12:22 PM	10.00	19.00	0.90	2.55	3.98
	Final	12:32 PM		19.90			
4	Initial	12:33 PM	10.00	19.00	0.91	2.55	4.03
	Final	12:43 PM		19.91			
5	Initial	12:44 PM	10.00	19.00	0.90	2.55	3.98
	Final	12:54 PM		19.90			
6	Initial	12:55 PM	10.00	19.00	0.90	2.55	3.98
	Final	1:05 PM		19.90			

Per County Standards, Infiltration Rate calculated as follows:

$$Q = \frac{\Delta H(60r)}{\Delta t(r + 2H_{avg})}$$

Where:
- Q = Infiltration Rate (in inches per hour)
- ΔH = Change in Height (Water Level) over the time interval
- r = Test Hole (Borehole) Radius
- Δt = Time Interval
- H_{avg} = Average Head Height over the time interval

Per County Standards, Infiltration Rate calculated as follows:

$$Q = \frac{\Delta H(60r)}{\Delta t(r + 2H_{avg})}$$

Where:
- Q = Infiltration Rate (in inches per hour)
- ΔH = Change in Height (Water Level) over the time interval
- r = Test Hole (Borehole) Radius
- Δt = Time Interval
- H_{avg} = Average Head Height over the time interval

Mr. Greybar

In accordance with your request, we have conducted a geotechnical investigation at the subject site. We are pleased to present this report summarizing the conclusions and recommendations developed from our investigation.

We sincerely appreciate the opportunity to be of service on this project. We look forward to providing additional consulting services during the course of the project. If we may be of further assistance in any manner, please contact our office.

Respectfully Submitted,

SOUTHERN CALIFORNIA GEOTECHNICAL, INC.

1.0 EXECUTIVE SUMMARY

Presented below is a brief summary of the conclusions and recommendations of this investigation. Since this summary is not all inclusive, it should be read in complete context with the entire report.

Geotechnical Design Considerations.

- Portions of the western and southern areas of the subject site are located within mapped zones of moderate liquefaction hazard. However, based on the subsurface profile identified in this report, the proposed grading, and the available groundwater data, liquefaction is not considered a design concern for this project.
- Artificial fill soils were encountered at several of the boring and trench locations, extending to depths of 1½ to 12± feet. These soils are considered to consist of undocumented fill materials. One of the borings identified artificial fill soils, extending to a depth of 29½± feet. The deeper fill soils are located within a former drainage canyon which appears to have been filled-in to establish the currently existing site grades. The fill soils are underlain by native alluvium, extending at least to the maximum depth explored of 50± feet.
- The proposed buildings will require cuts of up to 45 feet and fills of up to 65 feet to achieve the new building pad elevations.
- Field and laboratory testing indicates that some of the younger alluvial soils are moderately compressible, especially when exposed to the loads that will be exerted by the relatively deep new fills.
- The alluvial soils located within the southwest draining canyons and the existing undocumented fill materials are not considered suitable for support of the proposed fills and structures.
- Remedial grading is recommended to consist of overexcavation of existing fill, and alluvial soils, due to collapse/consolidation potential. These soils should be replaced as compacted fill.

Site Preparation

- Initial site preparation should include stripping of any surficial vegetation. The surficial vegetation, trees, and any organic soils should be properly disposed of off-site.
- Remedial grading is recommended to be performed within the new building pad areas. The existing soils within the building pad areas should be overexcavated to a depth of 6 feet below proposed pad grade. All existing artificial fill materials should also be removed from the new building pad areas. The soils within the proposed foundation influence zones should be overexcavated to a depth of at least 6 feet below proposed foundation bearing grades.
- Additional remedial grading (10 to 30 feet below existing grade) should be performed in the proposed deep fill areas to remove compressible alluvial soils that could result in significant settlements if allowed to remain in place.
- The recommended areas and depths of overexcavation are illustrated on Plate 4 of this report.
- The new pavement and flatwork subgrade soils are recommended to be scarified to a depth of 12± inches, moisture conditioned and recompacted to at least 90 percent of the ASTM D-1557 maximum dry density.

Building Foundations

- Conventional shallow foundations, supported in newly placed compacted fill.
- 3,000 lbs/ft^2 maximum allowable soil bearing pressure.
- Reinforcement consisting of at least four (4) No. 5 rebars (2 top and 2 bottom) in strip footings. Additional reinforcement may be necessary for structural considerations.

Building Floor Slabs

- Conventional Slab-on-Grade, 6 inches thick.
- Modulus of Subgrade Reaction: k = 100 psi/in.
- Reinforcement is not required for geotechnical conditions. The actual floor slab reinforcement should be determined by the structural engineer, based on the imposed slab loading.

Pavement Design Recommendations

ASPHALT PAVEMENTS (R=40)					
Materials	**Thickness (inches)**				
	Auto Parking and Auto Drive Lanes (TI = 4.0 to 5.0)	Truck Traffic			
		TI = 6.0	TI = 7.0	TI = 8.0	TI = 9.0
Asphalt Concrete	3	3½	4	5	5½
Aggregate Base	4	6	7	8	10
Compacted Subgrade	12	12	12	12	12

PORTLAND CEMENT CONCRETE PAVEMENTS (R=40)				
Materials	**Thickness (inches)**			
	Autos and Light Truck Traffic (TI = 6.0 or less)	Truck Traffic		
		TI = 7.0	TI = 8.0	TI = 9.0
PCC	5	5½	6½	8
Compacted Subgrade (95% minimum compaction)	12	12	12	12

2.0 SCOPE OF SERVICES

The scope of services performed for this project was in accordance with our Proposal No. 21P157, dated February 11, 2021 and our Change Order No. 21G133-CO, dated July 14, 2021. The scope of services included a visual site reconnaissance, subsurface exploration, field and laboratory testing, and geotechnical engineering analysis to provide criteria for preparing the design of the building foundations, building floor slab, and parking lot pavements along with site preparation recommendations and construction considerations for the proposed development. The evaluation of the environmental aspects of this site was beyond the scope of services for this geotechnical investigation.

Based on the grading plan prepared by Albert A. Webb Associates, the project will utilize new retaining walls ranging from 10 to 50± feet in height. These walls will be utilized in conjunction with new cut and fill slopes which will be required to establish the new site grades. It is recommended that an analysis be performed once grading and foundation plans become available to determine the stability of the proposed retaining wall and slope configurations. It may be necessary to perform an additional subsurface exploration in order to provide specific geotechnical design considerations for the new retaining wall systems.

3.0 SITE AND PROJECT DESCRIPTION

3.1 Site Conditions

The subject site is located on the south side of Cherry Valley Boulevard, 1,500± feet west of the intersection of Cherry Valley Boulevard and Fabian Lane in Beaumont, California. The site is bounded to the north by Cherry Valley Boulevard, to the east by single-family residences (SFRs) and vacant lots, to the south by Brookside Avenue, to the southwest by the Redlands Freeway (Interstate 10) and to the west by vacant land. The general location of the site is illustrated on the Site Location Map, enclosed as Plate 1 in Appendix A of this report.

The overall site consists of several irregular to rectangular-shaped parcels which total 178.4± acres in size. The site is presently developed with three (3) single-family residences and several small abandoned buildings located in the northeastern area of the site. Remnants of shade structures including Portland cement concrete panels and sawed-off poles are present throughout the northeastern areas of the site. Several above-ground storage tanks are also present throughout the northeastern area of the site. One of the smaller abandoned structures possesses a below-grade room with what appears to be a turbine. The remaining areas of the site are presently vacant and undeveloped. Five (5) circular to oval-shaped leech ponds are located in the west-central area of the site. Two (2) additional leech ponds are located in the south-central area of the site. Ground surface cover consist of exposed soil and moderate to dense native grass and weed growth. Several large trees are located in the southern areas of the site. Limited areas of trash and debris are located throughout the site.

Detailed topographic information was obtained from the conceptual grading plan prepared by Albert A. Webb Associates (Webb). Based on the provided plan, the northeastern to northern two-thirds of the site slopes downward to the southwest at a gradient of 4± percent. The seven (7) circular leech ponds located in the west-central and south-central areas of the site are surrounded by a berm that is 5± feet higher than the surrounding topography. The northwestern area of the site possesses several east-west and southeast-northwest trending drainage courses. The drainage features possess gradual to steep side walls with elevation differences of up to 15± feet below the surrounding topography. To the south of the leech pits, the site slopes towards the south to southwest at a gradient of 10± percent. The topography descends by 50± feet in this area. Another significant east-west trending drainage is located at the base of the descending slope, located in the southern-most region of the site. The drainage possesses gradual to steep side walls with an elevation difference up 10± feet below the surrounding topography. A hill, located to the southeast of this drainage, is approximately 20 to 30 feet higher than the surrounding topography. The hill possesses slope gradients ranging from 14 to 40± percent. To the south of the hill, the site topography slopes gently to the west at a gradient of 3.5± percent, where it meets up with a tributary drainage to the previously mentioned bisecting drainage. The area to the southwest of the bisecting drainage slopes to the west a gradient of 2.5± percent. Another hill with a north-facing descending slope is located at the southwest corner of the site. The slope has a gradient of 20± percent. The maximum site elevation is 2581± feet mean sea level (msl), in the northeast corner of the site. The minimum site elevation is 2406± feet msl, located in drainage swale channel located in the southern-most region of the site.

3.2 Proposed Development

Based on the conceptual site plan prepared by Webb, the site will be developed with three (3) new E-Commerce buildings. Building 1 will be 985,860± ft^2 in size, located in the western area of the site. Building 2 will be 1,254,000± ft^2 in size, located in the east-central region of the site. Lastly, Building 3 will be 358,370± ft^2 in size, located in the north-central area of the site. A cross-dock configuration will be constructed on Building 1 and Building 2, along the east/west and north/south building walls, respectively. Dock-high doors will be constructed along a portion of the southern building wall of Building 3. The buildings will be surrounded by asphaltic concrete pavements in the automobile parking and drive areas, Portland cement concrete (PCC) pavements in the truck court, and areas of concrete flatwork and landscape planters. Several new fill and cut slopes will be constructed along all permitters, as well as within the site. The new fill slopes will range from 10 to 40± feet in height and will possess slope inclinations not to exceed 2h:1v (horizontal to vertical). New retaining walls will also be required to establish the new site grades. The new retaining walls will possess maximum retained heights ranging from 10 to 50± feet.

Detailed structural information has not been provided. We assume that the new buildings will be single-story structures of tilt-up concrete construction, typically supported on a conventional shallow foundation system with a concrete slab-on-grade floor. Based on the assumed construction, maximum column and wall loads are expected to be on the order of 100 kips and 5 to 7 kips per linear foot, respectively.

No significant amounts of below-grade construction, such as basements or crawl spaces, are expected to be included in the proposed development. Based on the assumed topography, cuts of 45± feet and fills of up to 65± feet are expected to be necessary to achieve the proposed site grades.

4.0 SUBSURFACE EXPLORATION

4.1 Scope of Exploration/Sampling Methods

The subsurface exploration conducted for this project consisted of forty-four (44) borings advanced to depths of 10 to 50± feet, and seven (7) trenches excavated to depths of 6½ to 10½± feet below the existing site grades. Four (4) of the borings were advanced to a depth of 50± feet, as a part of the liquefaction evaluation. All of the borings and trenches were logged during the drilling and excavation by members of our staff.

The borings were advanced with hollow-stem augers, by a truck-mounted drilling rig. The trenches were excavated using a backhoe with a 36-inch-wide bucket. Representative bulk and undisturbed soil samples were taken during drilling. Relatively undisturbed samples were taken with a split barrel "California Sampler" containing a series of one inch long, 2.416± inch diameter brass rings. This sampling method is described in ASTM Test Method D-3550. Samples were also taken using a 1.4± inch inside diameter split spoon sampler, in general accordance with ASTM D-1586. Both of these samplers are driven into the ground with successive blows of a 140-pound weight falling 30 inches. The blow counts obtained during driving are recorded for further analysis. Bulk samples were collected in plastic bags to retain their original moisture content. The relatively undisturbed ring samples were placed in molded plastic sleeves that were then sealed and transported to our laboratory.

The approximate locations of the borings (identified as Boring Nos. B-1 through B-44) and trenches (identified as Trench Nos. T-1 through T-7) are indicated on the Boring and Trench Location Plan, included as Plate 2 in Appendix A of this report. The Boring and Trench Logs, which illustrate the conditions encountered at the boring and trench locations, as well as the results of some of the laboratory testing, are included in Appendix B.

4.2 Geotechnical Conditions

Pavements

Portland Cement Concrete (PCC) was encountered at the ground surface of Boring Nos. B-14, B-19 and B-25. The pavement sections consist of 2± inches of PCC. Boring Nos. B-19 and B-25 encountered 2± inches of slurry beneath the existing PCC pavements.

Artificial Fill

Artificial fill soils were encountered at the ground surface of several boring locations and one trench location, extending to depths of 1½ to 29½± feet below ground surface. The fill soils generally consist of loose to medium dense silty fine sand and clayey fine to medium sand. Occasional layers of medium dense silty fine to coarse sand and soft to stiff fine sandy clays were encountered. Varying amounts of fine root fibers were encountered in the silty fine sand layers. The fill soil possesses a disturbed and mottled appearance, resulting in their classification as

artificial fill. The deepest fill soils were encountered within Boring No. B-43, in the area of a former drainage channel. At this locations, the artificial fill soils included rubber and concrete debris.

Alluvium

Native alluvium was encountered beneath the artificial fill soils or at the ground surface at all of the boring locations. The alluvial soils extend to depths of 1½ to 12± feet below ground surface in the northern areas of the site, and 25 to 50± feet below ground surface in the southern areas of the site. The alluvial soils generally consist of loose to very dense silty fine sands and silty fine to medium sands. These soils possess fine root fibers near the ground surface and occasional porosity. Occasional layers of medium dense silty fine sand to fine sandy silt, fine to coarse sand, clayey silt, fine sandy silt and medium stiff silty clay were encountered in the deeper borings located in the southern areas.

Older Alluvium

Older alluvial deposits were encountered at the ground surface, or beneath the artificial fill and alluvium at all of the boring locations, extending to at least the maximum depth explored of 50± feet below ground surface. The older alluvial soils generally consist of medium dense to very dense silty fine sands, silty fine to medium sands, silty fine to coarse sands and silty fine sands to fine sandy silts. Several layers of medium dense to dense clayey fine sands, clayey fine to coarse sands and very stiff to hard fine sandy clays were encountered. Occasional layers of medium dense to dense fine sandy silts, fine to coarse sands and stiff fine to medium sandy clay were encountered.

Groundwater

Groundwater was not encountered at any of the boring or trench locations. Based on the lack of any water within the borings and trenches, and the moisture contents of the recovered soil samples, the static groundwater table is considered to have existed at a depth in excess of 50± feet below existing site grades at the time of the subsurface investigation.

As part of our research, we reviewed available groundwater data in order to determine the historic high groundwater level and recent groundwater level for the site. The primary reference used to determine the groundwater depths in this area is the California Department of Water Resources website, http://www.water.ca.gov/waterdatalibrary/. The nearest monitoring wells in this database are located in the northeast corner of the site. Water level readings within one of these monitoring wells indicates a historic high groundwater level of 317± feet below the ground surface in September 1990. Water level readings within another of these monitoring wells indicates a recent high groundwater level of 412± feet below the ground surface in December 2020.

4.3 Regional Geology

The subject site is located within the Peninsular Ranges province. The Peninsular Ranges province consists of several northwesterly-trending ranges in the southwestern California. The province is truncated to the north by the east-west trending Transverse Ranges. Prior to the mid-Mesozoic, the region was covered by seas and thick marine sedimentary and volcanic sequences were deposited. The bedrock geology that dominates the elevated areas of the Peninsular Ranges

consists of high-grade metamorphic rocks intruded by Mesozoic plutons. During the Cretaceous, extensive mountain building occurred during the emplacement of the southern California batholith. The Peninsular Ranges have been significantly disrupted by Tertiary and Quaternary strike-slip faulting along the Elsinore and San Jacinto faults. This tectonic activity has resulted in the present terrain.

4.4 Geologic Conditions

Regional geologic conditions were obtained from the Geologic Map of the El Casco 7.5' Quadrangle, Riverside County, California, by Thomas W. Dibblee, Jr., 2003 (Plate 3a) and Geologic and Geophysical Map of the El Casco 7.5' Quadrangle, Riverside County, California, with Accompanying Geologic-Map Database, Geologic Map by Jonathan C. Matti and Pamela M. Cossette, Digital Database by Douglas M. Hirshchberg, Jordan G. Matti and Pamela M. Cossette, 2015 (Plate 3b). Plate 3a indicates that the site is underlain by alluvial deposits (Map Symbol Qa) in the southwestern area of the site and older alluvium (Map Symbol Qoa) in the northeastern area of the site. The alluvium is described as alluvial sand, gravel and clay, covered by residual soil. The older alluvium is described as light reddish brown alluvial gravel and sand, of granitic and gneissic detritus of San Bernardino Mountains in north areas, and brownish gray in south areas. Plate 3b indicates that the site is underlain by young axial-valley deposits and very young wash deposits (Map Symbols Qvywm and Qya5) in southwestern area of the site and old alluvial-fan deposits and very old alluvial-fan deposits (Map Symbols Qof2 and Qvof3) in the northwestern area of the site. The very young wash deposits are described as very slightly to slightly consolidated sandy and gravelly sediment in active channels. The remaining units were not described in detail.

Based on the materials encountered at the boring locations, the northeastern portion of the site is underlain by older alluvium and the southwestern portion of the site is underlain by alluvium. It is in our opinion that the material encountered throughout the site is consistent with the mapped geologic units.

5.0 LABORATORY TESTING

The soil samples recovered from the subsurface exploration were returned to our laboratory for further testing to determine selected physical and engineering properties of the soils. The tests are briefly discussed below. It should be noted that the test results are specific to the actual samples tested, and variations could be expected at other locations and depths.

Classification

All recovered soil samples were classified using the Unified Soil Classification System (USCS), in accordance with ASTM D-2488. The field identifications were then supplemented with additional visual classifications and/or by laboratory testing. The USCS classifications are shown on the Boring Logs and are periodically referenced throughout this report.

Density and Moisture Content

The density has been determined for selected relatively undisturbed ring samples. These densities were determined in general accordance with the method presented in ASTM D-2937. The results are recorded as dry unit weight in pounds per cubic foot. The moisture contents are determined in accordance with ASTM D-2216, and are expressed as a percentage of the dry weight. These test results are presented on the Boring and Trench Logs.

Consolidation

Selected soil samples were tested to determine their consolidation potential, in accordance with ASTM D-2435. The testing apparatus is designed to accept either natural or remolded samples in a one-inch high ring, approximately 2.416 inches in diameter. Each sample is then loaded incrementally in a geometric progression and the resulting deflection is recorded at selected time intervals. Porous stones are in contact with the top and bottom of the sample to permit the addition or release of pore water. The samples are typically inundated with water at an intermediate load to determine their potential for collapse or heave. The results of the consolidation testing are plotted on Plates C-1 through C-42 in Appendix C of this report.

Expansion Index

The expansion potential of the on-site soils was determined in general accordance with ASTM D-4829. The testing apparatus is designed to accept a 4-inch diameter, 1-in high, remolded sample. The sample is initially remolded to 50± 1 percent saturation and then loaded with a surcharge equivalent to 144 pounds per square foot. The sample is then inundated with water and allowed to swell against the surcharge. The resultant swell or consolidation is recorded after a 24-hour period. The results of the EI testing are as follows:

Sample Identification	Expansion Index	Expansive Potential
B-20 @ 0 to 5 feet	45	Low
B-22 @ 0 to 5 feet	28	Low

Maximum Dry Density and Optimum Moisture Content

Representative bulk samples have been tested for their maximum dry density and optimum moisture content. The results have been obtained using the Modified Proctor procedure, per ASTM D-1557 and are presented on Plates C-43 through C-45 in Appendix C of this report. This test is generally used to compare the in-situ densities of undisturbed field samples, and for later compaction testing. Additional testing of other soil types or soil mixes may be necessary at a later date.

Direct Shear

Direct shear testing was performed on one representative sample to determine its shear strength parameters. The test was performed in accordance with ASTM D-3080. The testing apparatus is designed to accept either natural or remolded samples in a one-inch high ring, approximately 2.416 inches in diameter. Each of the three samples are then loaded with different normal loads and the resulting shear strength is determined for that particular normal load. The shearing of the samples is performed at a rate slow enough to permit the dissipation of excess pore water pressure. Porous stones are in contact with the top and bottom of the sample to permit the addition or release of pore water. The results of the direct shear test are presented on Plate C-46 in Appendix C of this report

Soluble Sulfates

Representative samples of the near-surface soil were submitted to a subcontracted analytical laboratory for determination of soluble sulfate content. Soluble sulfates are naturally present in soils, and if the concentration is high enough, can result in degradation of concrete which comes into contact with these soils. The results of the soluble sulfate testing are presented below, and are discussed further in a subsequent section of this report.

Sample Identification	Soluble Sulfates (%)	Sulfate Classification
B-4 @ 0 to 5 feet	0.001	Not Applicable (S0)
B-20 @ 0 to 5 feet	0.002	Not Applicable (S0)
B-25 @ 0 to 5 feet	0.002	Not Applicable (S0)

Corrosivity Testing

Representative bulk samples of the near-surface soils were submitted to a subcontracted corrosion engineering laboratory to identify potentially corrosive characteristics with respect to common construction materials. The corrosivity testing included a determination of the electrical resistivity, pH, and chloride and nitrate concentrations of the soils, as well as other tests. The results of some of these tests are presented below.

Sample Identification	Saturated Resistivity (ohm-cm)	pH	Chlorides (mg/kg)	Nitrates (mg/kg)
B-4 @ 0 to 5 feet	4,800	7.3	5.5	4.3
B-20 @ 0 to 5 feet	4,800	7.5	7.7	17
B-25 @ 0 to 5 feet	5,200	7.6	5.6	4.1

R-value Testing

R-value testing was conducted on one (1) representative soil sample recovered from the site. The R-(resistance) value was determined for representative soils samples in accordance with CA Test Method 301. This test provides a measure of the pavement support characteristics of the soils, and is used in the pavement thickness design procedure. The results of the R-value testing are as follows:

Sample Identification	**Soil Classification**	**R-Value**
B-4 @ 0 to 5 feet	Brown Silty Sand	60

6.0 CONCLUSIONS AND RECOMMENDATIONS

Based on the results of our review, field exploration, laboratory testing and geotechnical analysis, the proposed development is considered feasible from a geotechnical standpoint. The recommendations contained in this report should be taken into the design, construction, and grading considerations.

The recommendations are contingent upon all grading and foundation construction activities being monitored by the geotechnical engineer of record. The recommendations are provided with the assumption that an adequate program of client consultation, construction monitoring, and testing will be performed during the final design and construction phases to verify compliance with these recommendations. Maintaining Southern California Geotechnical, Inc., (SCG) as the geotechnical consultant from the beginning to the end of the project will provide continuity of services. The geotechnical engineering firm providing testing and observation services shall assume the responsibility of Geotechnical Engineer of Record.

The Grading Guide Specifications, included as Appendix D, should be considered part of this report, and should be incorporated into the project specifications. The contractor and/or owner of the development should bring to the attention of the geotechnical engineer any conditions that differ from those stated in this report, or which may be detrimental for the development.

6.1 Seismic Design Considerations

The subject site is located in an area which is subject to strong ground motions due to earthquakes. The performance of a site-specific seismic hazards analysis was beyond the scope of this investigation. However, numerous faults capable of producing significant ground motions are located near the subject site. Due to economic considerations, it is not generally considered reasonable to design a structure that is not susceptible to earthquake damage. Therefore, significant damage to structures may be unavoidable during large earthquakes. The proposed structures should, however, be designed to resist structural collapse and thereby provide reasonable protection from serious injury, catastrophic property damage and loss of life.

Faulting and Seismicity

Research of available maps indicates that the subject site is not located within an Alquist-Priolo Earthquake Fault Zone. In addition, our review of the Riverside County RCIT GIS website that the site is not located within a Riverside County fault zone. Therefore, the possibility of significant fault rupture on the site is considered to be low.

Seismic Design Parameters

Based on standards in place at the time of this report, the proposed development is expected to be designed in accordance with the requirements of the 2019 edition of the California Building Code (CBC), which was adopted on January 1, 2020. The 2019 California Building Code (CBC) provides procedures for earthquake resistant structural design that include considerations for on-site soil conditions, occupancy, and the configuration of the structure including the structural

system and height. The seismic design parameters presented below are based on the soil profile and the proximity of known faults with respect to the subject site.

The 2019 CBC Seismic Design Parameters have been generated using the SEAOC/OSHPD Seismic Design Maps Tool, a web-based software application available at the website www.seismicmaps.org. This software application calculates seismic design parameters in accordance with several building code reference documents, including ASCE 7-16, upon which the 2019 CBC is based. The application utilizes a database of risk-targeted maximum considered earthquake (MCE_R) site accelerations at 0.01-degree intervals for each of the code documents. The table below was created using data obtained from the application. The output generated from this program is included as Plate E-1 in Appendix E of this report.

The 2019 CBC requires that a site-specific ground motion study be performed in accordance with Section 11.4.8 of ASCE 7-16 for Site Class D sites with a mapped S_1 value greater than 0.2. However, Section 11.4.8 of ASCE 7-16 also indicates an exception to the requirement for a site-specific ground motion hazard analysis for certain structures on Site Class D sites. The commentary for Section 11 of ASCE 7-16 (Page 534 of Section C11 of ASCE 7-16) indicates that "In general, this exception effectively limits the requirements for site-specific hazard analysis to very tall and or flexible structures at Site Class D sites." **Based on our understanding of the proposed development, the seismic design parameters presented below were calculated assuming that the exception in Section 11.4.8 applies to the proposed structure at this site. However, the structural engineer should verify that this exception is applicable to the proposed structure.** Based on the exception, the spectral response accelerations presented below were calculated using the site coefficients (F_a and F_v) from Tables 1613.2.3(1) and 1613.2.3(2) presented in Section 16.4.4 of the 2019 CBC.

2019 CBC SEISMIC DESIGN PARAMETERS

Parameter		Value
Mapped Spectral Acceleration at 0.2 sec Period	S_S	2.091
Mapped Spectral Acceleration at 1.0 sec Period	S_1	0.718
Site Class	---	D
Site Modified Spectral Acceleration at 0.2 sec Period	S_{MS}	2.509
Site Modified Spectral Acceleration at 1.0 sec Period	S_{M1}	1.221
Design Spectral Acceleration at 0.2 sec Period	S_{DS}	1.673
Design Spectral Acceleration at 1.0 sec Period	S_{D1}	0.814

It should be noted that the site coefficient F_v and the parameters S_{M1} and S_{D1} were not included in the SEAOC/OSHPD Seismic Design Maps Tool output for the 2019 CBC. We calculated these parameters-based on Table 1613.2.3(2) in Section 16.4.4 of the 2019 CBC using the value of S_1 obtained from the Seismic Design Maps Tool, assuming that a site-specific ground motion hazards analysis is not required for the proposed building at this site.

Liquefaction

Liquefaction is the loss of the strength in generally cohesionless, saturated soils when the pore-water pressure induced in the soil by a seismic event becomes equal to or exceeds the overburden pressure. The primary factors which influence the potential for liquefaction include groundwater table elevation, soil type and grain size characteristics, relative density of the soil, initial confining pressure, and intensity and duration of ground shaking. The depth within which the occurrence of liquefaction may impact surface improvements is generally identified as the upper 50 feet below the existing ground surface. Liquefaction potential is greater in saturated, loose, poorly graded fine sands with a mean (d_{50}) grain size in the range of 0.075 to 0.2 mm (Seed and Idriss, 1971). Clayey (cohesive) soils or soils which possess clay particles (d<0.005mm) in excess of 20 percent (Seed and Idriss, 1982) are generally not considered to be susceptible to liquefaction, nor are those soils which are above the historic static groundwater table.

The Riverside County GIS website indicates that an isolated portions of the western and southern-most regions of the site are located within a zone of moderate liquefaction susceptibility. However, based on underlying soil conditions (which include moderate strength older alluvium), the proposed grading which includes fills of up to 65± feet, and the groundwater research performed for this site which indicates that the long-term groundwater table is considered to exist at a depth in excess of 50± feet, liquefaction is not considered to be a design concern for this project.

6.2 Geotechnical Design Considerations

General

The ground surface of the subject site is generally underlain by younger native alluvial soils, which are underlain at depth by moderate strength older alluvium. Some areas of the site are covered with a layer of undocumented fill soils extending to depths of 1½ to 12± feet. These soils are considered to consist of undocumented fill materials. One of the borings identified artificial fill soils, extending to a depth of 29½± feet. These deeper fill soils are located within a former drainage canyon which is expected to have been filled-in to establish the currently existing site grades. These undocumented fill soils are not suitable to support the foundations loads of the new structures, and should be removed in their entirety.

Based on the grading plan prepared by Webb, the proposed grading will require deep fill soils ranging from 15 to 65± feet in order to establish the new site grades in the western region of the site. The western region of the site includes several south-west drainage canyons which will require removal of the moderately compressible younger native alluvium, extending between the depths of 12 to 22± feet below the existing site grades. The existing older alluvium at greater depths possess moderate strengths and are expected to be encountered following removal of the younger alluvium. In addition, the deep cuts located in the eastern region of the site are expected to encounter the moderate strength alluvium. Some of the buildings, will be underlain by older alluvium on one side, and deep fill soils on the other side. This condition increases the possibility of excessive differential settlements. Remedial grading will be necessary to mitigate this condition.

Settlement

The recommended remedial grading will remove all of the existing undocumented fill soils and most of the near-surface compressible/collapsible younger alluvial soils, and replace these materials as compacted fill soils. The underlying moderate strength older alluvium which will remain in-place are note expected to be susceptible to settlement from the foundations of the proposed structures. Provided that the recommended remedial grading is completed, the post-construction static settlements of the proposed structures are expected to be within tolerable limits.

Deep Fill Areas

Based on the conceptual grading plan prepared by Webb, the proposed grading will include fills of up to 65± feet within the building pads. In order to reduce the settlement potential of the newly placed fill soils to acceptable levels and avoid excessive differential settlements, fill soils placed at depths greater than 20 feet below proposed pad grade within the building pads should be compacted to at least 95 percent of the ASTM D-1557 maximum dry density.

Settlement of Deep Fill Soils

Subsequent to the proposed grading, the proposed development areas will be underlain by engineered fill soils (design plus remedial), extending to depths of 50 to 85± feet. The primary settlement associated with these fill soils is expected to occur relatively quickly due to the generally granular nature of the on-site soils. Minor amounts of additional settlement may occur due to secondary consolidation effects. The extent of secondary consolidation is difficult to assess precisely, and will be reduced by the proposed mitigation measures recommended herein, but may be in the range of 0.1 to 0.3 percent of the fill thickness. Based on the differential fill thickness that will exist across the building footprints, the structural design will need to consider the distortions that could be caused by the secondary consolidation of the fill soils. Provided that the grading and foundation design recommendations presented in this report are implemented, these settlements are expected to be within the structural tolerances of the proposed buildings.

This report includes recommendations to install settlement monuments within the deep fill areas of Buildings 1 and 2. These monuments will be used to verify that primary consolidation of the remaining alluvial soils is complete, prior to initiating construction of the new buildings.

Cut/Fill Transitions

The conceptual grading plan indicates that several cut/fill transitions will be created within the proposed building pads by the proposed grading. The differing support conditions of the native soils versus the newly compacted fill soils may result in excessive differential settlements if not mitigated. Remedial grading will be required to eliminate the cut/fill transitions which will occur at building pad and foundation bearing grade as well as to reduce the inclinations of the underlying cut/fill contacts.

Expansion

The near-surface soils consist of silty sands and sandy silts with no appreciable clay content. However, some isolated strata of sandy clays and clayey sands were encountered. Expansion

Index (EI) values at the site range from 28 to 45. Mass grading of the site is expected to blend the on-site soils, resulting in a very low to low expansive potential. We recommend that additional expansion index testing be performed at the time of rough grading in order to confirm the expansion potential of the near-surface soils at this site.

Slope Stability

The grading plan indicates that the new slopes (both cut and fill) will occur at inclinations of 2h:1v or flatter. Newly constructed fill slopes, comprised of properly compacted engineered fill, at inclinations of 2h:1v will possess adequate gross and surficial stability.

Cut slopes excavated within the existing granular alluvial soils may be subject to surficial instability due to the lack of cohesion within these materials. Therefore, stability fills may be required within these areas. This condition may affect the proposed cut slopes at the site. The need for stability fills should be determined by SCG as part of the future detailed grading plan review.

Based on the grading plan prepared by Webb, new retaining walls ranging from 10 to 50± feet in height will be utilized in conjunction with new cut and fill slopes at the site. An additional review of the proposed site configuration may be required once detailed grading and foundation plans become available in order to determine the stability of the new retaining wall systems. An additional subsurface exploration may also be required as part of the analysis of the new retaining wall structures.

Soluble Sulfates

The result of the soluble sulfate testing indicates that the selected samples of the on-site soils possess concentrations of sulfates that correspond to Class S0 with respect to the American Concrete Institute (ACI) Publication 318-05 Building Code Requirements for Structural Concrete and Commentary, Section 4.3. Therefore, specialized concrete mix designs are not considered to be necessary, with regard to sulfate protection purposes. It is, however, recommended that additional soluble sulfate testing be conducted at the completion of rough grading to verify the soluble sulfate concentrations of the soils which are present at pad grade within the building areas.

Corrosion Potential

The results of laboratory testing indicate that the tested samples of the on-site soils possess saturated resistivity values of 4,800 to 5,200 ohm-cm, and pH values of 7.3 to 7.6. These test results have been evaluated in accordance with guidelines published by the Ductile Iron Pipe Research Association (DIPRA). The DIPRA guidelines consist of a point system by which characteristics of the soils are used to quantify the corrosivity characteristics of the site. Sulfides, and redox potential are factors that are also used in the evaluation procedure. We have evaluated the corrosivity characteristics of the on-site soils using resistivity, pH, and moisture content. Based on these factors, and utilizing the DIPRA procedure, the on-site soils are not considered to be corrosive to ductile iron pipe.

Relatively low concentrations (5.5 to 7.7 mg/kg) of chlorides were detected in the samples submitted for corrosivity testing. In general, soils possessing chloride concentrations in excess of 500 parts per million (ppm) are considered to be corrosive with respect to steel reinforcement

within reinforced concrete. Based on the lack of any significant chlorides in the tested samples, the site is considered to have a C1 chloride exposure in accordance with the American Concrete Institute (ACI) Publication 318 Building Code Requirements for Structural Concrete and Commentary. Therefore, a specialized concrete mix design for reinforced concrete for protection against chloride exposure is not considered warranted.

Nitrates present in soil can be corrosive to copper tubing at concentrations greater than 50 mg/kg. The tested samples possess nitrate concentrations ranging from 4.1 to 17 mg/kg. Based on this test result, the on-site soils are not considered to be corrosive to copper pipe.

It should be noted that SCG does not practice in the area of corrosion engineering. Therefore, the client may also wish to contact a corrosion engineer to provide a more thorough evaluation of these conditions.

Shrinkage/Subsidence

Removal and recompaction of the near-surface fill and younger alluvial soils (located in the southwestern region of the site) is estimated to result in an average shrinkage of 6 to 14 percent. This assumes average compaction of 92 percent within the new engineered fill soils. Removal and recompaction of the existing older alluvial soils located in the south and west regions of the site is estimated to result in an average shrinkage of 0 to 8 percent. Engineering fills more than 20 feet below finished grade, where 95 percent compaction is recommended, should be assumed to result in shrinkage of 13 to 20 percent. It should be noted that these shrinkage estimates are based on dry density testing performed on small-diameter samples taken at the boring locations. If a more accurate and precise shrinkage estimate is desired, SCG can perform a shrinkage study involving several excavated test pits where in-place densities are determined using in-situ testing methods instead of laboratory density testing on small-diameter samples. Please contact SCG for details and a cost estimate regarding a shrinkage study, if desired.

These estimates are based on previous experience with nearby projects and the subsurface conditions encountered at the boring and trench locations. The actual amount of subsidence is expected to be variable and will be dependent on the type of machinery used, repetitions of use, and dynamic effects, all of which are difficult to assess precisely.

Foundation and Grading Plan Review

Based on our review of the preliminary grading plans prepared by Webb, new retaining walls with maximum heights of up to 50± feet will be constructed as part of the new development. It is recommended that additional review of the global stability of the proposed site grading be performed by SCG once more detailed rough grading plans become available. An additional subsurface exploration may be required to evaluate the geotechnical design considerations of the retaining wall and new slope configurations.

It is recommended that we be provided with copies of all future foundation and grading plans, when they become available, for review with regard to the conclusions, recommendations, and assumptions contained within this report.

6.3 Site Grading Recommendations

The grading recommendations presented below are based on the subsurface conditions encountered at the boring and trench locations, and our understanding of the proposed development. We recommend that all grading activities be completed in accordance with the Grading Guide Specifications included as Appendix D of this report, unless superseded by site-specific recommendations presented below.

Site Stripping and Demolition

Initial site stripping should include removal of any surficial vegetation and topsoil. This should include any weeds, grasses, shrubs, and trees. Removal of trees should also include any associated root masses. The actual extent of site stripping should be determined in the field by the geotechnical engineer, based on the organic content and stability of the materials encountered. The scattered trash and debris that is present on the site should be collected and disposed of off-site.

Demolition of minor existing improvements such as buildings, retaining walls, concrete slabs and foundations will be required. Demolition debris should be disposed of off-site. Concrete may also be crushed to a maximum 2-inch particle size and incorporated into new structural fills.

Treatment of Existing Soils: Building Pads

Remedial grading should be performed within the proposed development area in order to remove all of the existing undocumented fill soils. Based on conditions encountered at the boring and trench locations, the undocumented fill soils extend to depths of up to 12± feet. At one of the boring locations, the existing undocumented fill soils extend to a depth of 29½± feet. It is possible that undocumented fill soils may extend to greater depths in unexplored areas of the site. Additional remedial grading should be performed in the deep proposed fill areas (the west and southwest areas of Buildings 1 and 2) to remove the compressible younger alluvial soils that could result in significant settlements if allowed to remain in place. These recommended overexcavations generally range from 12 to 22± feet below existing grade.

Within the influence zones of the new foundations, the overexcavation should extend to a depth of at least 6 feet below proposed foundation bearing grades. The overexcavation area should extend at least 5 feet beyond the building and foundation perimeters, and to an extent equal to the depth of fill below the new foundations. If the proposed structure incorporates any exterior columns (such as for a canopy or overhang) the area of overexcavation should also encompass these areas.

Additional remedial grading is also recommended to mitigate the native/fill transitions that will be created by the proposed grading. There for the proposed buildings within the cut portion of the site are recommended to be overexcavated to a depth of 10 feet below proposed pad grade and 6 feet below footing grade.

The recommended areas and depths of overexcavation are illustrated on Plate 4 of this report.

To mitigate the relatively steep inclination of the underlying cut/fill contact in the areas of the southwest draining canyons, benching of the sidewalls will be required during fill placement. The horizontal extent of the benching should be sufficient to reduce the inclination of the native fill contact to 3h:1v or flatter. This additional benching is not required outside the areas of the proposed building foundation influence zones.

Following completion of the overexcavations, the subgrade should be evaluated by the geotechnical engineer to verify its suitability to serve as the structural fill subgrade. Some localized areas of deeper excavation may be required if loose, porous, or low-density materials are encountered at the base of the overexcavation. Materials suitable to serve as the structural fill subgrade within the building area should consist of moderate strength alluvial soils which possess an in-situ density equal to at least 85 percent of the ASTM D-1557 maximum dry density. These materials should be moisture conditioned to 0 to 4 percent above optimum moisture content prior to placement of any new fill soils. The previously excavated soils may then be replaced as compacted structural fill.

Deep Fill Areas

In order to reduce the settlement potential of the newly placed fill soils to acceptable levels and avoid excessive differential settlements, fill soils placed at depths greater than 20 feet below proposed building pad grades should be compacted to at least 95 percent of the ASTM D-1557 maximum dry density.

Treatment of Existing Soils: Cut and Fill Slopes

New cut and fill slopes will be constructed within and around the perimeter of the project. All slopes should be at an inclination of 2h:1v or flatter. A keyway should be excavated at the toe of new fill slopes which are not located in fill areas. The keyway should be at least 15 feet wide and 3 feet deep. The recommended width of the keyway is based on 1.5 times the width of typical grading equipment. If smaller equipment is utilized, a smaller keyway may be suitable, at the discretion of the geotechnical engineer. The base of the keyway should slope at least 1 foot downward into the slope. Following completion of the keyway cut, the subgrade soils should be evaluated by the geotechnical engineer to verify that the keyway is founded into competent materials. The resulting subgrade soils should then be scarified to a depth of 10 to 12 inches, moisture conditioned to 0 to 4 percent above optimum moisture content and recompacted. During construction of the new fill slopes, any existing slopes should be benched in accordance with the detail presented on Plate D-4. Benches less than 4 feet in height may be used at the discretion of the geotechnical engineer.

Stability fills for cut slopes will provide a more uniform appearance and allow landscaping on the slope. Should a stability fill for cut slope be necessary, the recommendations for the stability fill will be the same as the recommendations for the fill slopes, mentioned above.

Treatment of Existing Soils: Retaining Walls and Site Walls

The existing soils within the areas of any proposed retaining walls and site walls should be overexcavated to a depth of 3 feet below foundation bearing grade and replaced as compacted structural fill as discussed above for the proposed building pad. Any undocumented fill soils or disturbed native alluvium within any of these foundation areas should be removed in their

entirety. Retaining wall footings may also be supported directly within bedrock materials, with no overexcavation required. The overexcavation areas should extend at least 5 feet beyond the foundation perimeters, and to an extent equal to the depth of fill below the new foundations. Any erection pads for tilt-up concrete walls are considered to be part of the foundation system. Therefore, these overexcavation recommendations are applicable to erection pads. The overexcavation subgrade soils should be evaluated by the geotechnical engineer prior to scarifying, moisture conditioning to within 0 to 4 percent above the optimum moisture content, and recompacting the upper 12 inches of exposed subgrade soils. The previously excavated soils may then be replaced as compacted structural fill.

If the full lateral recommended remedial grading cannot be completed for the proposed retaining walls and site walls located along property lines, the foundations for those walls should be designed using a reduced allowable bearing pressure. Furthermore, the contractor should take necessary precautions to protect the adjacent structures during rough grading. Specialized grading techniques, such as A-B-C slot cuts, will likely be required during remedial grading. The geotechnical engineer of record should be contacted if additional recommendations, such as shoring design recommendations, are required during grading.

Treatment of Existing Soils: Flatwork, Parking and Drive Areas

Based on economic considerations, overexcavation of the existing near-surface existing soils in the new flatwork, parking and drive areas is not considered warranted, with the exception of areas where lower strength or unstable soils are identified by the geotechnical engineer during grading. Subgrade preparation in the new flatwork, parking and drive areas should initially consist of removal of all soils disturbed during stripping and demolition operations.

The geotechnical engineer should then evaluate the subgrade to identify any areas of additional unsuitable soils. Any such materials should be removed to a level of firm and unyielding soil. The exposed subgrade soils should then be scarified to a depth of 12± inches, moisture conditioned to 0 to 4 percent above the optimum moisture content, and recompacted to at least 90 percent of the ASTM D-1557 maximum dry density. Based on the presence of variable strength surficial soils throughout the site, it is expected that some isolated areas of additional overexcavation may be required to remove zones of lower strength, unsuitable soils.

The grading recommendations presented above for the proposed flatwork, parking and drive areas assume that the owner and/or developer can tolerate minor amounts of settlement within these areas. The grading recommendations presented above do not mitigate the extent of undocumented fill or compressible/collapsible native alluvium in the flatwork, parking and drive areas. As such, some settlement and associated pavement distress could occur. Typically, repair of such distressed areas involves significantly lower costs than completely mitigating these soils at the time of construction. If the owner cannot tolerate the risk of such settlements, the flatwork, parking and drive areas should be overexcavated to a depth of 2 feet below proposed pavement subgrade elevation, with the resulting soils replaced as compacted structural fill.

Fill Placement

- Fill soils should be placed in thin (6± inches), near-horizontal lifts, moisture conditioned to 0 to 4 percent of the optimum moisture content, and compacted.

- On-site soils may be used for fill provided they are cleaned of any debris to the satisfaction of the geotechnical engineer.
- All grading and fill placement activities should be completed in accordance with the requirements of the current CBC and the grading code of the city of Beaumont.
- All fill soils should be compacted to at least 90 percent of the ASTM D-1557 maximum dry density, unless noted otherwise. Fill soils placed at depths greater than 20 feet below proposed rough grade should be compacted to at least 95 percent of the ASTM d-1557 maximum dry density. Fill soils should be well mixed.
- Compaction tests should be performed periodically by the geotechnical engineer as random verification of compaction and moisture content. These tests are intended to aid the contractor. Since the tests are taken at discrete locations and depths, they may not be indicative of the entire fill and therefore should not relieve the contractor of his responsibility to meet the job specifications.

Imported Structural Fill

All imported structural fill should consist of very low to non-expansive (EI < 20), well graded soils possessing at least 10 percent fines (that portion of the sample passing the No. 200 sieve). Additional specifications for structural fill are presented in the Grading Guide Specifications, included as Appendix D.

Utility Trench Backfill

In general, all utility trench backfill should be compacted to at least 90 percent of the ASTM D-1557 maximum dry density. Compacted trench backfill should conform to the requirements of the local grading code, and more restrictive requirements may be indicated by the city of Beaumont. All utility trench backfills should be witnessed by the geotechnical engineer. The trench backfill soils should be compaction tested where possible; probed and visually evaluated elsewhere.

Utility trenches which parallel a footing, and extending below a 1h:1v plane projected from the outside edge of the footing should be backfilled with structural fill soils, compacted to at least 90 percent of the ASTM D-1557 standard. Pea gravel backfill should not be used for these trenches. Any soils used to backfill voids around subsurface utility structures, such as manholes or vaults, should be placed as compacted structural fill. If it is not practical to place compacted fill in these areas, then such void spaces may be backfilled with lean concrete slurry. Uncompacted pea gravel or sand is not recommended for backfilling these voids since these materials have a potential to settle and thereby cause distress of pavements placed around these subterranean structures.

6.4 Construction Considerations

Excavation Considerations

The near-surface soils generally consist of silty sands and clayey sands. These materials will be subject to caving within shallow excavations. Where caving occurs within shallow excavations, flattened excavation slopes may be sufficient to provide excavation stability. On a preliminary basis, temporary excavation slopes should be made no steeper than 2h:1v. Deeper excavations may require some form of external stabilization such as shoring or bracing. Maintaining adequate

moisture content within the near-surface soils will improve excavation stability. All excavation activities on this site should be conducted in accordance with Cal-OSHA regulations.

Groundwater

The static groundwater table is considered to exist at a depth greater than 50± feet or more below the existing grades. Therefore, groundwater is not expected to impact the grading or foundation construction activities.

Slopes

Cut slopes within the native alluvium, and manufactured fill slopes will be prone to erosion. Provisions for surface drainage, terrace drains, slope planting and other measures in accordance with CBC requirements should be provided to improve long-term protection of the new slopes. These measures may include installation and maintenance of Hydro seed, polymers or other erosion control measures to provide slope protection until healthy plant grown is established.

Subdrains

Subdrains may be required at the site, particularly in the canyon/drainage areas where deep removals will be required. Specific subdrain recommendations can be provided based on a review of the final development plans, and based on conditions encountered during grading.

Settlement Monitoring

Based upon our understanding of proposed grading, fills on the order of about 80± feet deep (design plus remedial grading will be required. Engineered fills deeper than 20 feet should incorporate a minimum relative compaction of 95 percent, and a moisture content of at least two percentage points above optimum moisture content. A settlement monitoring program should be implemented, consisting of the surveying of surface monuments to monitor settlement of alluvial soils left in-place and/or proposed fills deeper than 30 feet (design plus remedial grading). Survey monument readings for both deep fill areas and for fill over compressible natural ground (Qal) should be conducted following the completion of fill placement. Survey monument locations should be selected by the geotechnical consultant. Survey readings should be taken weekly for the first month and on a weekly basis thereafter until vertical movement of the fill mass achieve 90 percent of primary compression, begin secondary compression or the estimated remaining settlement is less than one inch. Construction of proposed structures should not commence until approved by the geotechnical consultant based on the results of the settlement monitoring. The survey bench marks used for the monitoring should be confirmed with the geotechnical consultant prior to initial readings being performed.

6.5 Foundation Design and Construction

Based on the preceding grading recommendations, it is assumed that the new building pads will be underlain by newly placed structural fill soils, extending to a depth of at least 6 feet below foundation bearing grade, which are underlain by native alluvial soils. Based on this subsurface profile, the proposed structures may be supported on shallow foundations.

Conventional Spread Footing Foundation Design Parameters

New square and rectangular footings may be designed as follows:

- Maximum, net allowable soil bearing pressure: 3,000 lbs/ft^2.
- Minimum wall/column footing width: 14 inches/24 inches.
- Minimum longitudinal steel reinforcement within strip footings: Four (4) No. 5 rebars (2 top and 2 bottom), due to the differential fill depths.
- Minimum foundation embedment: 12 inches into newly placed structural fill soils, and at least 24 inches below adjacent exterior grade.
- It is recommended that the perimeter building foundations be continuous across all exterior doorways. Any flatwork adjacent to the exterior doors should be doweled into the perimeter foundations in a manner determined by the structural engineer.

The allowable bearing pressure presented above may be increased by one-third when considering short duration wind or seismic loads. The minimum steel reinforcement recommended above is based on geotechnical considerations; additional reinforcement may be necessary for structural considerations. The actual design of the foundations should be determined by the structural engineer.

Foundation Construction

The foundation subgrade soils should be evaluated at the time of overexcavation, as discussed in Section 6.3 of this report. It is further recommended that the foundation subgrade soils be evaluated by the geotechnical engineer immediately prior to steel or concrete placement. Soils suitable for direct foundation support should consist of newly placed structural fill, compacted to at least 90 percent of the ASTM D-1557 maximum dry density. Any unsuitable materials should be removed to a depth of suitable bearing compacted structural fill or suitable native alluvium (where reduced bearing pressures are utilized), with the resulting excavations backfilled with compacted fill soils. As an alternative, lean concrete slurry (500 to 1,500 psi) may be used to backfill such isolated overexcavations.

The foundation subgrade soils should also be properly moisture conditioned to 0 to 4 percent above the Modified Proctor optimum, to a depth of at least 12 inches below bearing grade. Since it is typically not feasible to increase the moisture content of the floor slab and foundation subgrade soils once rough grading has been completed, care should be taken to maintain the moisture content of the building pad subgrade soils throughout the construction process.

Estimated Foundation Settlements

Post-construction total and differential settlements of shallow foundations designed and constructed in accordance with the previously presented recommendations are estimated to be less than 1.0 and 0.5 inches, respectively. Differential movements are expected to occur over a 60-foot span, thereby resulting in an angular distortion of less than 0.002 inches per inch (1/500 deflection ratio).

Lateral Load Resistance

Lateral load resistance will be developed by a combination of friction acting at the base of foundations and slabs and the passive earth pressure developed by footings below grade. The following friction and passive pressure may be used to resist lateral forces:

- Passive Earth Pressure: 300 lbs/ft^3
- Friction Coefficient: 0.30

These are allowable values, and include a factor of safety. When combining friction and passive resistance, the passive pressure component should be reduced by one-third. These values assume that footings will be poured directly against compacted structural fill. The maximum allowable passive pressure is 2,500 lbs/ft^2.

6.6 Floor Slab Design and Construction

Subgrades which will support new floor slabs should be prepared in accordance with the recommendations contained in the ***Site Grading Recommendations*** section of this report. Based on the anticipated grading which will occur at this site, the floors of the proposed structures may be constructed as a conventional slabs-on-grade supported on newly placed structural fill, which is underlain by moderate strength alluvium. Based on geotechnical considerations, the floor slabs may be designed as follows:

- Minimum slab thickness: 6 inches.

- Modulus of Subgrade Reaction: k = 100 psi/in.

- Minimum slab reinforcement: Reinforcement is not required for geotechnical conditions. However, slab reinforcement may be required for structural design considerations. The actual floor slab reinforcement should be determined by the structural engineer, based upon the imposed loading, and the settlement estimates provided previously.

- Slab underlayment: If moisture sensitive floor coverings will be used then minimum slab underlayment should consist of a moisture vapor barrier constructed below the entire slab area where such moisture sensitive floor coverings are expected. The moisture vapor barrier should meet or exceed the Class A rating as defined by ASTM E 1745-97 and have a permeance rating less than 0.01 perms as described in ASTM E 96-95 and ASTM E 154-88. A polyolefin material such as 15 mil Stego® Wrap Vapor Barrier or equivalent will meet these specifications. The moisture vapor barrier should be properly constructed in accordance with all applicable manufacturer specifications. Given that a rock free subgrade is anticipated and that a capillary break is not required, sand below the barrier is not required. The need for sand and/or the amount of sand above the moisture vapor barrier should be specified by the structural engineer or concrete contractor. The selection of sand above the barrier is not a geotechnical engineering issue and hence outside our purview. Where moisture sensitive floor coverings are not anticipated, the vapor barrier may be eliminated.

- Moisture condition the floor slab subgrade soils to 0 to 4 percent above the Modified Proctor optimum moisture content, to a depth of 12 inches. The moisture content of the floor slab subgrade soils should be verified by the geotechnical engineer within 24 hours prior to concrete placement.

- Proper concrete curing techniques should be utilized to reduce the potential for slab curling or the formation of excessive shrinkage cracks.

- The floor slabs should be structurally connected to the foundations as detailed by the structural engineer.

The actual design of the floor slab should be completed by the structural engineer to verify adequate thickness and reinforcement.

6.7 Retaining Wall Design and Construction

The grading plan prepared by Webb indicates that the site will utilize several retaining walls along the perimeters of the site. Retaining walls are also expected within the truck dock areas of the proposed buildings. The parameters recommended for use in the design of these walls are presented below.

Retaining Wall Design Parameters

Based on the soil conditions encountered at the trench and boring locations, the following parameters may be used in the design of new retaining walls for this site. We have provided parameters assuming the use of on-site soils for retaining wall backfill. These near-surface soils generally consist of sands and silty sands and occasional clayey sands. These materials are expected to possess friction angles of at least 30 degrees when compacted to 90 percent of the ASTM-1557 maximum dry density.

If desired, SCG could provide design parameters for an alternative select backfill material behind the retaining walls. The use of select backfill material could result in lower lateral earth pressures. In order to use the design parameters for the imported select fill, this material must be placed within the entire active failure wedge. This wedge is defined as extending from the heel of the retaining wall upwards at an angle of approximately 60° from horizontal. If select backfill material behind the retaining wall is desired, SCG should be contacted for supplementary recommendations.

RETAINING WALL DESIGN PARAMETERS

Design Parameter		Soil Type
		On-Site Silty Sands
Internal Friction Angle (ϕ)		30°
Unit Weight		132 lbs/ft^3
Equivalent Fluid Pressure:	Active Condition (level backfill)	44 lbs/ft^3
	At-Rest Condition (level backfill)	66 lbs/ft^3
	Active Condition (2h:1v backfill)	71 lbs/ft^3

The walls should be designed using a soil-footing coefficient of friction of 0.30 and an equivalent passive pressure of 300 lbs/ft^3. The structural engineer should incorporate appropriate factors of safety in the design of the retaining walls.

The active earth pressure may be used for the design of retaining walls that do not directly support structures or support soils that in turn support structures and which will be allowed to deflect. The at-rest earth pressure should be used for walls that will not be allowed to deflect such as those which will support foundation bearing soils, or which will support foundation loads directly.

Where the soils on the toe side of the retaining wall are not covered by a "hard" surface such as a structure or pavement, the upper 1 foot of soil should be neglected when calculating passive resistance due to the potential for the material to become disturbed or degraded during the life of the structure.

Seismic Lateral Earth Pressures

In accordance with the 2019 CBC, any retaining walls more than 6 feet in height must be designed for seismic lateral earth pressures. The recommended seismic pressure distribution is triangular in shape, assumed to occur at the top of the wall, decreasing to 0 at the base of the wall. For a level backfill condition behind the top of the wall, the seismic lateral earth pressure is 44H lbs/ft^2, where H is the overall height of the wall. Where the ground surface above the wall consists of a 2h:1v sloping condition, the seismic lateral earth pressure is 71H lbs/ft^2. The seismic pressure distribution is based on the Mononobe-Okabe equation, utilizing the PGA_M ground acceleration of 1.024g. The 2019 CBC does not provide definitive guidance on determination of the design acceleration to be used in generating the seismic lateral earth pressure. In accordance with standard geotechnical practice, we have calculated the design acceleration as $^2/_3$ of the PGA_M. However, for combinations of high ground motion and steep slopes above the wall, the Mononobe-Okabe equation gives unrealistic high estimates of active earth pressures. Therefore, the seismic earth pressure for the sloping condition presented above was calculated using a design acceleration equal to 50% of the PGA_M.

Retaining Wall Foundation Design

The retaining wall foundations should be underlain by at least 3 feet of newly placed structural fill. Foundations to support new retaining walls should be designed in accordance with the general Foundation Design Parameters presented in a previous section of this report.

Backfill Material

On-site sands and silty sands may be used to backfill the retaining walls. However, all backfill material placed within 3 feet of the back wall face should have a particle size no greater than 3 inches. The retaining wall backfill materials should be well graded.

It is recommended that a minimum 1-foot thick layer of free-draining granular material (less than 5 percent passing the No. 200 sieve) be placed against the face of the retaining walls. This material should extend from the top of the retaining wall footing to within 1 foot of the ground surface on the back side of the retaining wall. This material should be approved by the geotechnical engineer. In lieu of the 1-foot thick layer of free-draining material, a properly installed prefabricated drainage composite such as the MiraDRAIN 6000XL (or approved equivalent), which is specifically designed for use behind retaining walls, may be used. If the layer of free-draining material is not covered by an impermeable surface, such as a structure or pavement, a 12-inch thick layer of a low permeability soil should be placed over the backfill to reduce surface water migration to the underlying soils. The layer of free draining granular material should be separated from the backfill soils by a suitable geotextile, approved by the geotechnical engineer.

All retaining wall backfill should be placed and compacted under engineering controlled conditions in the necessary layer thicknesses to ensure an in-place density between 90 and 93 percent of the maximum dry density as determined by the Modified Proctor test (ASTM D1557-91). Care should be taken to avoid over-compaction of the soils behind the retaining walls, and the use of heavy compaction equipment should be avoided.

Subsurface Drainage

As previously indicated, the retaining wall design parameters are based upon drained backfill conditions. Consequently, some form of permanent drainage system will be necessary in conjunction with the appropriate backfill material. Subsurface drainage may consist of either:

- A weep hole drainage system typically consisting of a series of 4-inch diameter holes in the wall situated slightly above the ground surface elevation on the exposed side of the wall and at an approximate 20-foot on-center spacing. The weep holes should include a 2 cubic foot pocket of open graded gravel, surrounded by an approved geotextile fabric, at each weep hole location.

- A 4-inch diameter perforated pipe surrounded by 2 cubic feet of gravel per linear foot of drain placed behind the wall, above the retaining wall footing. The gravel layer should be wrapped in a suitable geotextile fabric to reduce the potential for migration of fines. The footing drain should be extended to daylight or tied into a storm drainage system.

6.8 Pavement Design Parameters

Site preparation in the pavement area should be completed as previously recommended in the ***Site Grading Recommendations*** section of this report. The subsequent pavement recommendations assume proper drainage and construction monitoring, and are based on either PCA or CALTRANS design parameters for a twenty (20) year design period. However, these designs also assume a routine pavement maintenance program to obtain the anticipated 20-year pavement service life.

Pavement Subgrades

It is anticipated that the new pavements will be primarily supported on a layer of compacted structural fill, consisting of scarified, thoroughly moisture conditioned and recompacted existing soils. The near-surface soils generally consist of silty sands and clayey sands. Based on their classification, these materials are expected to possess good pavement support characteristics. The results of the R-value testing indicate that a sample of these soils possesses an R-value of 60. In order to allow for areas of lower strength soils, the subsequent pavement design is based upon an assumed R-value of 40. Any fill material imported to the site should have support characteristics equal to or greater than that of the on-site soils and be placed and compacted under engineering-controlled conditions. It is recommended that R-value testing be performed after completion of rough grading. Depending upon the results of the R-value testing, it may be feasible to use thinner pavement sections in some areas of the site.

Asphaltic Concrete

Presented below are the recommended thicknesses for new flexible pavement structures consisting of asphaltic concrete over a granular base. The pavement designs are based on the traffic indices (TI's) indicated. The client and/or civil engineer should verify that these TI's are representative of the anticipated traffic volumes. If the client and/or civil engineer determine that the expected traffic volume will exceed the applicable traffic index, we should be contacted for supplementary recommendations. The design traffic indices equate to the following approximate daily traffic volumes over a 20-year design life, assuming six operational traffic days per week.

Traffic Index	No. of Heavy Trucks per Day
4.0	0
5.0	1
6.0	3
7.0	11
8.0	35
9.0	93

For the purpose of the traffic volumes indicated above, a truck is defined as a 5-axle tractor trailer unit with one 8-kip axle and two 32-kip tandem axles. All of the traffic indices allow for 1,000 automobiles per day.

ASPHALT PAVEMENTS (R=40)					
Materials	**Thickness (inches)**				
	Auto Parking and Auto Drive Lanes (TI = 4.0 to 5.0)	Truck Traffic			
		TI = 6.0	TI = 7.0	TI = 8.0	TI = 9.0
Asphalt Concrete	3	3½	4	5	5½
Aggregate Base	4	6	7	8	10
Compacted Subgrade	12	12	12	12	12

The aggregate base course should be compacted to at least 95 percent of the ASTM D-1557 maximum dry density. The asphaltic concrete should be compacted to at least 95 percent of the Marshall maximum density, as determined by ASTM D-2726. The aggregate base course may consist of crushed aggregate base (CAB) or crushed miscellaneous base (CMB), which is a recycled gravel, asphalt and concrete material. The gradation, R-Value, Sand Equivalent, and Percentage Wear of the CAB or CMB should comply with appropriate specifications contained in the current edition of the "Greenbook" Standard Specifications for Public Works Construction.

Portland Cement Concrete

The preparation of the subgrade soils within concrete pavement areas should be performed as previously described for proposed asphalt pavement areas. The minimum recommended thicknesses for the Portland Cement Concrete pavement sections are as follows:

PORTLAND CEMENT CONCRETE PAVEMENTS (R=40)				
Materials	**Thickness (inches)**			
	Autos and Light Truck Traffic (TI = 6.0 or less)	Truck Traffic		
		TI = 7.0	TI = 8.0	TI = 9.0
PCC	5	5½	6½	8
Compacted Subgrade (95% minimum compaction)	12	12	12	12

The concrete should have a 28-day compressive strength of at least 3,000 psi. Any reinforcement within the PCC pavements should be determined by the project structural engineer. The maximum joint spacing within all of the PCC pavements is recommended to be equal to or less than 30 times the pavement thickness.

7.0 GENERAL COMMENTS

This report has been prepared as an instrument of service for use by the client, in order to aid in the evaluation of this property and to assist the architects and engineers in the design and preparation of the project plans and specifications. This report may be provided to the contractor(s) and other design consultants to disclose information relative to the project. However, this report is not intended to be utilized as a specification in and of itself, without appropriate interpretation by the project architect, civil engineer, and/or structural engineer. The reproduction and distribution of this report must be authorized by the client and Southern California Geotechnical, Inc. Furthermore, any reliance on this report by an unauthorized third party is at such party's sole risk, and we accept no responsibility for damage or loss which may occur. The client(s)' reliance upon this report is subject to the Engineering Services Agreement, incorporated into our proposal for this project.

The analysis of this site was based on a subsurface profile interpolated from limited discrete soil samples. While the materials encountered in the project area are considered to be representative of the total area, some variations should be expected between boring locations and sample depths. If the conditions encountered during construction vary significantly from those detailed herein, we should be contacted immediately to determine if the conditions alter the recommendations contained herein.

This report has been based on assumed or provided characteristics of the proposed development. It is recommended that the owner, client, architect, structural engineer, and civil engineer carefully review these assumptions to ensure that they are consistent with the characteristics of the proposed development. If discrepancies exist, they should be brought to our attention to verify that they do not affect the conclusions and recommendations contained herein. We also recommend that the project plans and specifications be submitted to our office for review to verify that our recommendations have been correctly interpreted.

The analysis, conclusions, and recommendations contained within this report have been promulgated in accordance with generally accepted professional geotechnical engineering practice. No other warranty is implied or expressed.

SAMPLE TYPE	GRAPHICAL SYMBOL	SAMPLE DESCRIPTION
AUGER		SAMPLE COLLECTED FROM AUGER CUTTINGS, NO FIELD MEASUREMENT OF SOIL STRENGTH. (DISTURBED)
CORE		ROCK CORE SAMPLE: TYPICALLY TAKEN WITH A DIAMOND-TIPPED CORE BARREL. TYPICALLY USED ONLY IN HIGHLY CONSOLIDATED BEDROCK.
GRAB		SOIL SAMPLE TAKEN WITH NO SPECIALIZED EQUIPMENT, SUCH AS FROM A STOCKPILE OR THE GROUND SURFACE. (DISTURBED)
CS		CALIFORNIA SAMPLER: 2-1/2 INCH I.D. SPLIT BARREL SAMPLER, LINED WITH 1-INCH HIGH BRASS RINGS. DRIVEN WITH SPT HAMMER. (RELATIVELY UNDISTURBED)
NSR		NO RECOVERY: THE SAMPLING ATTEMPT DID NOT RESULT IN RECOVERY OF ANY SIGNIFICANT SOIL OR ROCK MATERIAL.
SPT		STANDARD PENETRATION TEST: SAMPLER IS A 1.4 INCH INSIDE DIAMETER SPLIT BARREL, DRIVEN 18 INCHES WITH THE SPT HAMMER. (DISTURBED)
SH		SHELBY TUBE: TAKEN WITH A THIN WALL SAMPLE TUBE, PUSHED INTO THE SOIL AND THEN EXTRACTED. (UNDISTURBED)
VANE		VANE SHEAR TEST: SOIL STRENGTH OBTAINED USING A 4 BLADED SHEAR DEVICE. TYPICALLY USED IN SOFT CLAYS-NO SAMPLE RECOVERED.

COLUMN DESCRIPTIONS

DEPTH: Distance in feet below the ground surface.

SAMPLE: Sample Type as depicted above.

BLOW COUNT: Number of blows required to advance the sampler 12 inches using a 140 lb hammer with a 30-inch drop. 50/3" indicates penetration refusal (>50 blows) at 3 inches. WH indicates that the weight of the hammer was sufficient to push the sampler 6 inches or more.

POCKET PEN.: Approximate shear strength of a cohesive soil sample as measured by pocket penetrometer.

GRAPHIC LOG: Graphic Soil Symbol as depicted on the following page.

DRY DENSITY: Dry density of an undisturbed or relatively undisturbed sample in lbs/ft^3.

MOISTURE CONTENT: Moisture content of a soil sample, expressed as a percentage of the dry weight.

LIQUID LIMIT: The moisture content above which a soil behaves as a liquid.

PLASTIC LIMIT: The moisture content above which a soil behaves as a plastic.

PASSING #200 SIEVE: The percentage of the sample finer than the #200 standard sieve.

UNCONFINED SHEAR: The shear strength of a cohesive soil sample, as measured in the unconfined state.

SOIL CLASSIFICATION CHART

MAJOR DIVISIONS			SYMBOLS		TYPICAL DESCRIPTIONS
			GRAPH	LETTER	
COARSE GRAINED SOILS MORE THAN 50% OF MATERIAL IS LARGER THAN NO. 200 SIEVE SIZE	GRAVEL AND GRAVELLY SOILS MORE THAN 50% OF COARSE FRACTION RETAINED ON NO. 4 SIEVE	CLEAN GRAVELS (LITTLE OR NO FINES)		GW	WELL-GRADED GRAVELS, GRAVEL - SAND MIXTURES, LITTLE OR NO FINES
				GP	POORLY-GRADED GRAVELS, GRAVEL - SAND MIXTURES, LITTLE OR NO FINES
		GRAVELS WITH FINES (APPRECIABLE AMOUNT OF FINES)		GM	SILTY GRAVELS, GRAVEL - SAND - SILT MIXTURES
				GC	CLAYEY GRAVELS, GRAVEL - SAND - CLAY MIXTURES
	SAND AND SANDY SOILS MORE THAN 50% OF COARSE FRACTION PASSING ON NO. 4 SIEVE	CLEAN SANDS (LITTLE OR NO FINES)		SW	WELL-GRADED SANDS, GRAVELLY SANDS, LITTLE OR NO FINES
				SP	POORLY-GRADED SANDS, GRAVELLY SAND, LITTLE OR NO FINES
		SANDS WITH FINES (APPRECIABLE AMOUNT OF FINES)		SM	SILTY SANDS, SAND - SILT MIXTURES
				SC	CLAYEY SANDS, SAND - CLAY MIXTURES
FINE GRAINED SOILS MORE THAN 50% OF MATERIAL IS SMALLER THAN NO. 200 SIEVE SIZE	SILTS AND CLAYS	LIQUID LIMIT LESS THAN 50		ML	INORGANIC SILTS AND VERY FINE SANDS, ROCK FLOUR, SILTY OR CLAYEY FINE SANDS OR CLAYEY SILTS WITH SLIGHT PLASTICITY
				CL	INORGANIC CLAYS OF LOW TO MEDIUM PLASTICITY, GRAVELLY CLAYS, SANDY CLAYS, SILTY CLAYS, LEAN CLAYS
				OL	ORGANIC SILTS AND ORGANIC SILTY CLAYS OF LOW PLASTICITY
	SILTS AND CLAYS	LIQUID LIMIT GREATER THAN 50		MH	INORGANIC SILTS, MICACEOUS OR DIATOMACEOUS FINE SAND OR SILTY SOILS
				CH	INORGANIC CLAYS OF HIGH PLASTICITY
				OH	ORGANIC CLAYS OF MEDIUM TO HIGH PLASTICITY, ORGANIC SILTS
HIGHLY ORGANIC SOILS				PT	PEAT, HUMUS, SWAMP SOILS WITH HIGH ORGANIC CONTENTS

NOTE: DUAL SYMBOLS ARE USED TO INDICATE BORDERLINE SOIL CLASSIFICATIONS

APPENDIX D

GRADING GUIDE SPECIFICATIONS

These grading guide specifications are intended to provide typical procedures for grading operations. They are intended to supplement the recommendations contained in the geotechnical investigation report for this project. Should the recommendations in the geotechnical investigation report conflict with the grading guide specifications, the more site specific recommendations in the geotechnical investigation report will govern.

General

- The Earthwork Contractor is responsible for the satisfactory completion of all earthwork in accordance with the plans and geotechnical reports, and in accordance with city, county, and applicable building codes.

- The Geotechnical Engineer is the representative of the Owner/Builder for the purpose of implementing the report recommendations and guidelines. These duties are not intended to relieve the Earthwork Contractor of any responsibility to perform in a workman-like manner, nor is the Geotechnical Engineer to direct the grading equipment or personnel employed by the Contractor.

- The Earthwork Contractor is required to notify the Geotechnical Engineer of the anticipated work and schedule so that testing and inspections can be provided. If necessary, work may be stopped and redone if personnel have not been scheduled in advance.

- The Earthwork Contractor is required to have suitable and sufficient equipment on the job-site to process, moisture condition, mix and compact the amount of fill being placed to the approved compaction. In addition, suitable support equipment should be available to conform with recommendations and guidelines in this report.

- Canyon cleanouts, overexcavation areas, processed ground to receive fill, key excavations, subdrains and benches should be observed by the Geotechnical Engineer prior to placement of any fill. It is the Earthwork Contractor's responsibility to notify the Geotechnical Engineer of areas that are ready for inspection.

- Excavation, filling, and subgrade preparation should be performed in a manner and sequence that will provide drainage at all times and proper control of erosion. Precipitation, springs, and seepage water encountered shall be pumped or drained to provide a suitable working surface. The Geotechnical Engineer must be informed of springs or water seepage encountered during grading or foundation construction for possible revision to the recommended construction procedures and/or installation of subdrains.

Site Preparation

- The Earthwork Contractor is responsible for all clearing, grubbing, stripping and site preparation for the project in accordance with the recommendations of the Geotechnical Engineer.

- If any materials or areas are encountered by the Earthwork Contractor which are suspected of having toxic or environmentally sensitive contamination, the Geotechnical Engineer and Owner/Builder should be notified immediately.

- Major vegetation should be stripped and disposed of off-site. This includes trees, brush, heavy grasses and any materials considered unsuitable by the Geotechnical Engineer.

- Underground structures such as basements, cesspools or septic disposal systems, mining shafts, tunnels, wells and pipelines should be removed under the inspection of the Geotechnical Engineer and recommendations provided by the Geotechnical Engineer and/or city, county or state agencies. If such structures are known or found, the Geotechnical Engineer should be notified as soon as possible so that recommendations can be formulated.

- Any topsoil, slopewash, colluvium, alluvium and rock materials which are considered unsuitable by the Geotechnical Engineer should be removed prior to fill placement.

- Remaining voids created during site clearing caused by removal of trees, foundations basements, irrigation facilities, etc., should be excavated and filled with compacted fill.

- Subsequent to clearing and removals, areas to receive fill should be scarified to a depth of 10 to 12 inches, moisture conditioned and compacted

- The moisture condition of the processed ground should be at or slightly above the optimum moisture content as determined by the Geotechnical Engineer. Depending upon field conditions, this may require air drying or watering together with mixing and/or discing.

Compacted Fills

- Soil materials imported to or excavated on the property may be utilized in the fill, provided each material has been determined to be suitable in the opinion of the Geotechnical Engineer. Unless otherwise approved by the Geotechnical Engineer, all fill materials shall be free of deleterious, organic, or frozen matter, shall contain no chemicals that may result in the material being classified as “contaminated,” and shall be very low to non-expansive with a maximum expansion index (EI) of 50. The top 12 inches of the compacted fill should have a maximum particle size of 3 inches, and all underlying compacted fill material a maximum 6-inch particle size, except as noted below.

- All soils should be evaluated and tested by the Geotechnical Engineer. Materials with high expansion potential, low strength, poor gradation or containing organic materials may require removal from the site or selective placement and/or mixing to the satisfaction of the Geotechnical Engineer.

- Rock fragments or rocks less than 6 inches in their largest dimensions, or as otherwise determined by the Geotechnical Engineer, may be used in compacted fill, provided the distribution and placement is satisfactory in the opinion of the Geotechnical Engineer.

- Rock fragments or rocks greater than 12 inches should be taken off-site or placed in accordance with recommendations and in areas designated as suitable by the Geotechnical Engineer. These materials should be placed in accordance with Plate D-8 of these Grading Guide Specifications and in accordance with the following recommendations:

    - Rocks 12 inches or more in diameter should be placed in rows at least 15 feet apart, 15 feet from the edge of the fill, and 10 feet or more below subgrade. Spaces should be left between each rock fragment to provide for placement and compaction of soil around the fragments.

    - Fill materials consisting of soil meeting the minimum moisture content requirements and free of oversize material should be placed between and over the rows of rock or

concrete. Ample water and compactive effort should be applied to the fill materials as they are placed in order that all of the voids between each of the fragments are filled and compacted to the specified density.

- Subsequent rows of rocks should be placed such that they are not directly above a row placed in the previous lift of fill. A minimum 5-foot offset between rows is recommended.

- To facilitate future trenching, oversized material should not be placed within the range of foundation excavations, future utilities or other underground construction unless specifically approved by the soil engineer and the developer/owner representative.

- Fill materials approved by the Geotechnical Engineer should be placed in areas previously prepared to receive fill and in evenly placed, near horizontal layers at about 6 to 8 inches in loose thickness, or as otherwise determined by the Geotechnical Engineer for the project.

- Each layer should be moisture conditioned to optimum moisture content, or slightly above, as directed by the Geotechnical Engineer. After proper mixing and/or drying, to evenly distribute the moisture, the layers should be compacted to at least 90 percent of the maximum dry density in compliance with ASTM D-1557-78 unless otherwise indicated.

- Density and moisture content testing should be performed by the Geotechnical Engineer at random intervals and locations as determined by the Geotechnical Engineer. These tests are intended as an aid to the Earthwork Contractor, so he can evaluate his workmanship, equipment effectiveness and site conditions. The Earthwork Contractor is responsible for compaction as required by the Geotechnical Report(s) and governmental agencies.

- Fill areas unused for a period of time may require moisture conditioning, processing and recompaction prior to the start of additional filling. The Earthwork Contractor should notify the Geotechnical Engineer of his intent so that an evaluation can be made.

- Fill placed on ground sloping at a 5-to-1 inclination (horizontal-to-vertical) or steeper should be benched into bedrock or other suitable materials, as directed by the Geotechnical Engineer. Typical details of benching are illustrated on Plates D-2, D-4, and D-5.

- Cut/fill transition lots should have the cut portion overexcavated to a depth of at least 3 feet and rebuilt with fill (see Plate D-1), as determined by the Geotechnical Engineer.

- All cut lots should be inspected by the Geotechnical Engineer for fracturing and other bedrock conditions. If necessary, the pads should be overexcavated to a depth of 3 feet and rebuilt with a uniform, more cohesive soil type to impede moisture penetration.

- Cut portions of pad areas above buttresses or stabilizations should be overexcavated to a depth of 3 feet and rebuilt with uniform, more cohesive compacted fill to impede moisture penetration.

- Non-structural fill adjacent to structural fill should typically be placed in unison to provide lateral support. Backfill along walls must be placed and compacted with care to ensure that excessive unbalanced lateral pressures do not develop. The type of fill material placed adjacent to below grade walls must be properly tested and approved by the Geotechnical Engineer with consideration of the lateral earth pressure used in the design.

Foundations

- The foundation influence zone is defined as extending one foot horizontally from the outside edge of a footing, and proceeding downward at a ½ horizontal to 1 vertical (0.5:1) inclination.

- Where overexcavation beneath a footing subgrade is necessary, it should be conducted so as to encompass the entire foundation influence zone, as described above.

- Compacted fill adjacent to exterior footings should extend at least 12 inches above foundation bearing grade. Compacted fill within the interior of structures should extend to the floor subgrade elevation.

Fill Slopes

- The placement and compaction of fill described above applies to all fill slopes. Slope compaction should be accomplished by overfilling the slope, adequately compacting the fill in even layers, including the overfilled zone and cutting the slope back to expose the compacted core

- Slope compaction may also be achieved by backrolling the slope adequately every 2 to 4 vertical feet during the filling process as well as requiring the earth moving and compaction equipment to work close to the top of the slope. Upon completion of slope construction, the slope face should be compacted with a sheepsfoot connected to a sideboom and then grid rolled. This method of slope compaction should only be used if approved by the Geotechnical Engineer.

- Sandy soils lacking in adequate cohesion may be unstable for a finished slope condition and therefore should not be placed within 15 horizontal feet of the slope face.

- All fill slopes should be keyed into bedrock or other suitable material. Fill keys should be at least 15 feet wide and inclined at 2 percent into the slope. For slopes higher than 30 feet, the fill key width should be equal to one-half the height of the slope (see Plate D-5).

- All fill keys should be cleared of loose slough material prior to geotechnical inspection and should be approved by the Geotechnical Engineer and governmental agencies prior to filling.

- The cut portion of fill over cut slopes should be made first and inspected by the Geotechnical Engineer for possible stabilization requirements. The fill portion should be adequately keyed through all surficial soils and into bedrock or suitable material. Soils should be removed from the transition zone between the cut and fill portions (see Plate D-2).

Cut Slopes

- All cut slopes should be inspected by the Geotechnical Engineer to determine the need for stabilization. The Earthwork Contractor should notify the Geotechnical Engineer when slope cutting is in progress at intervals of 10 vertical feet. Failure to notify may result in a delay in recommendations.

- Cut slopes exposing loose, cohesionless sands should be reported to the Geotechnical Engineer for possible stabilization recommendations.

- All stabilization excavations should be cleared of loose slough material prior to geotechnical inspection. Stakes should be provided by the Civil Engineer to verify the location and dimensions of the key. A typical stabilization fill detail is shown on Plate D-5.

- Stabilization key excavations should be provided with subdrains. Typical subdrain details are shown on Plates D-6.

Subdrains

- Subdrains may be required in canyons and swales where fill placement is proposed. Typical subdrain details for canyons are shown on Plate D-3. Subdrains should be installed after approval of removals and before filling, as determined by the Soils Engineer.

- Plastic pipe may be used for subdrains provided it is Schedule 40 or SDR 35 or equivalent. Pipe should be protected against breakage, typically by placement in a square-cut (backhoe) trench or as recommended by the manufacturer.

- Filter material for subdrains should conform to CALTRANS Specification 68-1.025 or as approved by the Geotechnical Engineer for the specific site conditions. Clean ¾-inch crushed rock may be used provided it is wrapped in an acceptable filter cloth and approved by the Geotechnical Engineer. Pipe diameters should be 6 inches for runs up to 500 feet and 8 inches for the downstream continuations of longer runs. Four-inch diameter pipe may be used in buttress and stabilization fills.

BUILDING 1 BIORETENTION BASIN

Basin V_{BMP} Calculation

Designer:	EP
Date:	4/11/2022
Project:	Beaumont Summit Station Builidng 1
Location:	South of Cherry Valley Blvd and North of Brookside Ave
Area:	DMA 1

(1)	Drawdown Time =	48	hrs
(2)	Basin Bottom Area=	5064	ft^2
(3)	Infiltration Rate (i)=	1.6	in/hr

$$V_{BMP}(ft^3) = Drawdown(hr) \times i\left(\frac{in}{hr}\right) \times \left(\frac{1ft}{12in}\right) \times Bottom\ Area(ft^2)$$

V_{BMP} = 32410 ft^3

***A minimum infiltration rate of 1.6 in/hr was assumed for the engineered media.The entire basin will drain within the maximum drawdown time of 48 hours.

BUILDING 2 INFILTRATION BASIN

Infiltration Basin - Design Procedure (Rev. 03-2012)	BMP ID	Legend:	Required Entries / Calculated Cells
Company Name: Albert A. Webb Associates			Date: 12/13/2021
Designed by: EP			County/City Case No.:

Design Volume

a) Tributary area (BMP subarea)	A_T =	50	acres
b) Enter V_{BMP} determined from Section 2.1 of this Handbook	V_{BMP}=	144,000	ft^3

Maximum Depth

a) Infiltration rate	I =	11.5	in/hr
b) Factor of Safety (See Table 1, Appendix A: "Infiltration Testing" from this BMP Handbook)	FS =	3	
c) Calculate D_1 $D_1 = \frac{I\ (in/hr) \times 72\ hrs}{12\ (in/ft) \times FS}$	D_1 =	23.0	ft
d) Enter the depth of freeboard (at least 1 ft)		1	ft
e) Enter depth to historic high ground water (measured from **top** of basin)		18	ft
f) Enter depth to top of bedrock or impermeable layer (measured from **top** of basin)		21	ft
g) D_2 is the smaller of: Depth to groundwater - (10 ft + freeboard) and Depth to impermeable layer - (5 ft + freeboard)	D_2 =	7.0	ft
h) D_{MAX} is the smaller value of D_1 and D_2 but shall not exceed 5 feet	D_{MAX} =	7.0	ft

Basin Geometry

a) Basin side slopes (no steeper than 4:1)	z =	4	:1
b) Proposed basin depth (excluding freeboard)	d_B =	4	ft
c) Minimum bottom surface area of basin ($A_S = V_{BMP}/d_B$)	A_S =	36000	ft^2
d) Proposed Design Surface Area	A_D =	106388	ft^2

Forebay

a) Forebay volume (minimum 0.5% V_{BMP})	Volume =	720	ft^3
b) Forebay depth (height of berm/splashwall. 1 foot min.)	Depth =	1	ft
c) Forebay surface area (minimum)	Area =	720	ft^2
d) Full height notch-type weir	Width (W) =	6.0	in

NOTE: See "Beaumont Summit Station - Building 2 Preliminary WQMP" for basin design details. The infiltration basin has been sized for the Building 2 site VBMP of 144,000 cf. Approx. 75,940 cf of the Building 2 VBMP is proposed to be pumped to the basin for treatment once the Building 2 VBMP has fully infiltrated.

BUILDING 1 LID HARVEST & USE

LID Harvest & Reuse V_{BMP} Calculation

Designer:	EP
Date:	4/11/2022
Project:	Beaumont Summit Station Builidng 1
Location:	South of Cherry Valley Blvd and North of Brookside Ave
Area:	LID Harvest & Reuse

(1)	Irrigation Cycle=	12	hrs
(2)	Area of Vegetation=	20150	ft^2
(3)	Infiltration Rate (i)=	1.6	in/hr

$$V_{BMP}(ft^3) = Irrigation\ Time(hr) \times i\left(\frac{in}{hr}\right) \times \left(\frac{1ft}{12in}\right) \times Area(ft^2)$$

V_{BMP} = 32240 ft^3

***A minimum infiltration rate of 1.6 in/hr was assumed for the engineered media.The entire basin will drain within the maximum drawdown time of 48 hours.

106.40	1.50	159.60

100 YEAR Area rainfall data:

Area(Ac.)[1]	Rainfall(In)[2]	Weighting[1*2]
106.40	6.50	691.60

STORM EVENT (YEAR) = 2.00
Area Averaged 2-Year Rainfall = 1.500(In)
Area Averaged 100-Year Rainfall = 6.500(In)

Point rain (area averaged) = 1.500(In)
Areal adjustment factor = 99.98 %
Adjusted average point rain = 1.500(In)

Sub-Area Data:

Area(Ac.)	Runoff Index	Impervious %
106.400	77.30	0.120

Total Area Entered = 106.40(Ac.)

RI AMC2	RI AMC-1	Infil. Rate (In/Hr)	Impervious (Dec.%)	Adj. Infil. Rate (In/Hr)	Area% (Dec.)	F (In/Hr)

77.3	59.8	0.472	0.120	0.421	1.000	0.421
					Sum (F) =	0.421

Area averaged mean soil loss (F) (In/Hr) = 0.421
Minimum soil loss rate ((In/Hr)) = 0.211
(for 24 hour storm duration)
Soil low loss rate (decimal) = 0.800
